This handout includes copies of the slides that will be used in lectures and more detailed notes on the selected topics. These notes do not constitute a complete transcript of all the lectures and they are not a substitute for text books. They are intended to give a reasonable synopsis of the subjects discussed, but they give neither complete descriptions nor all the background material.

Advanced Graphics & Image Processing

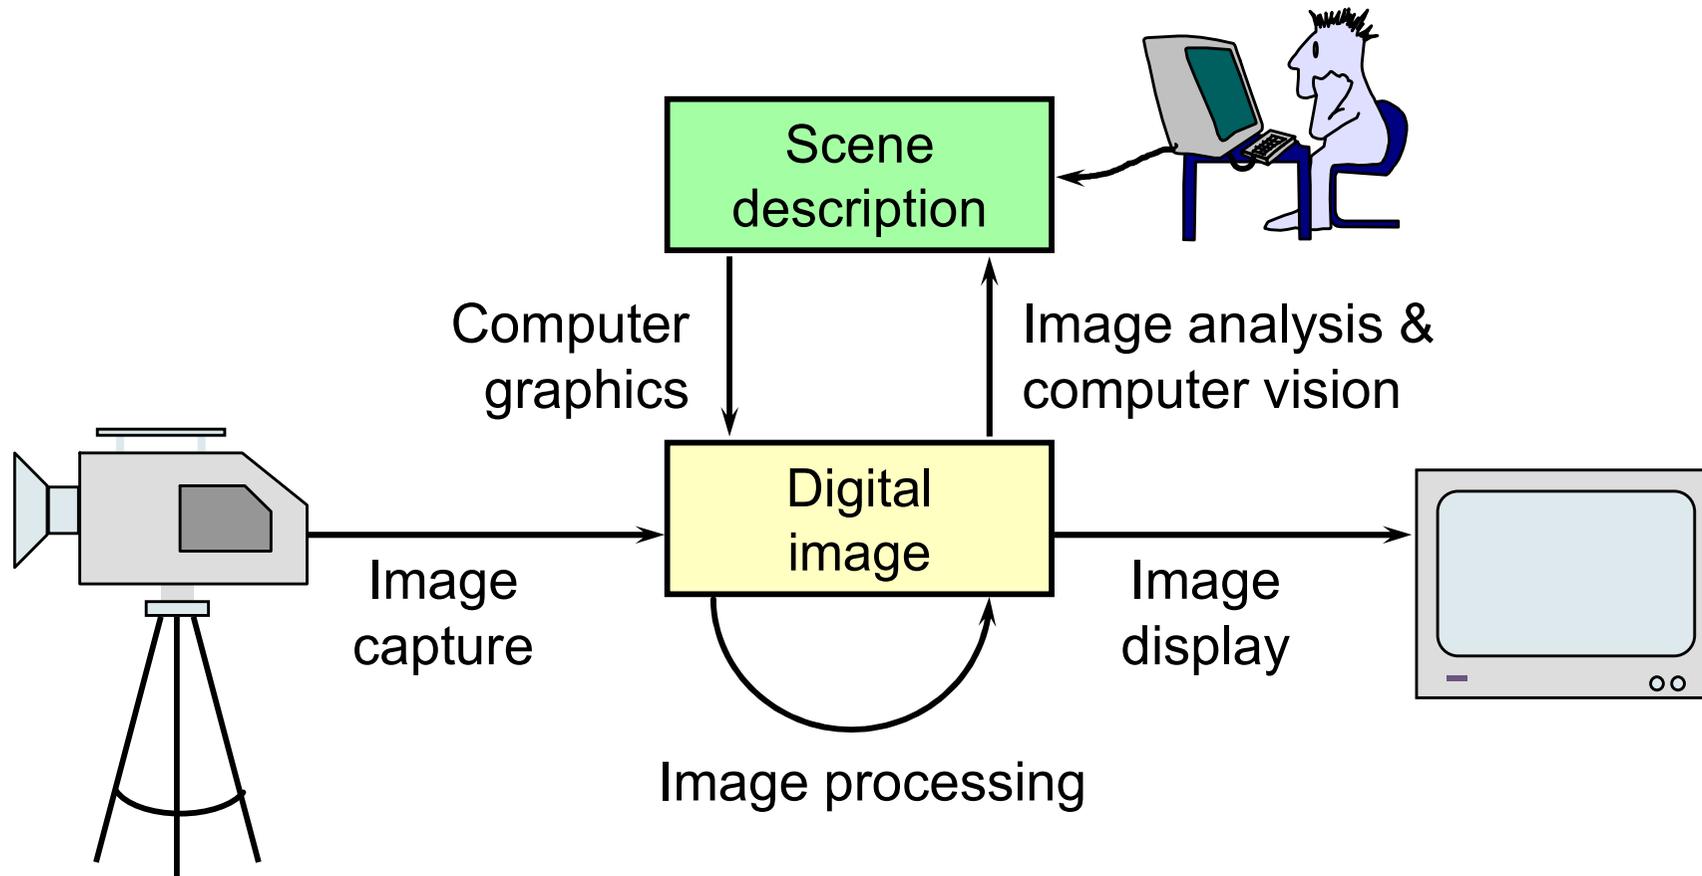

Introduction to Image Processing

Part 1/2 – Images, pixels and sampling

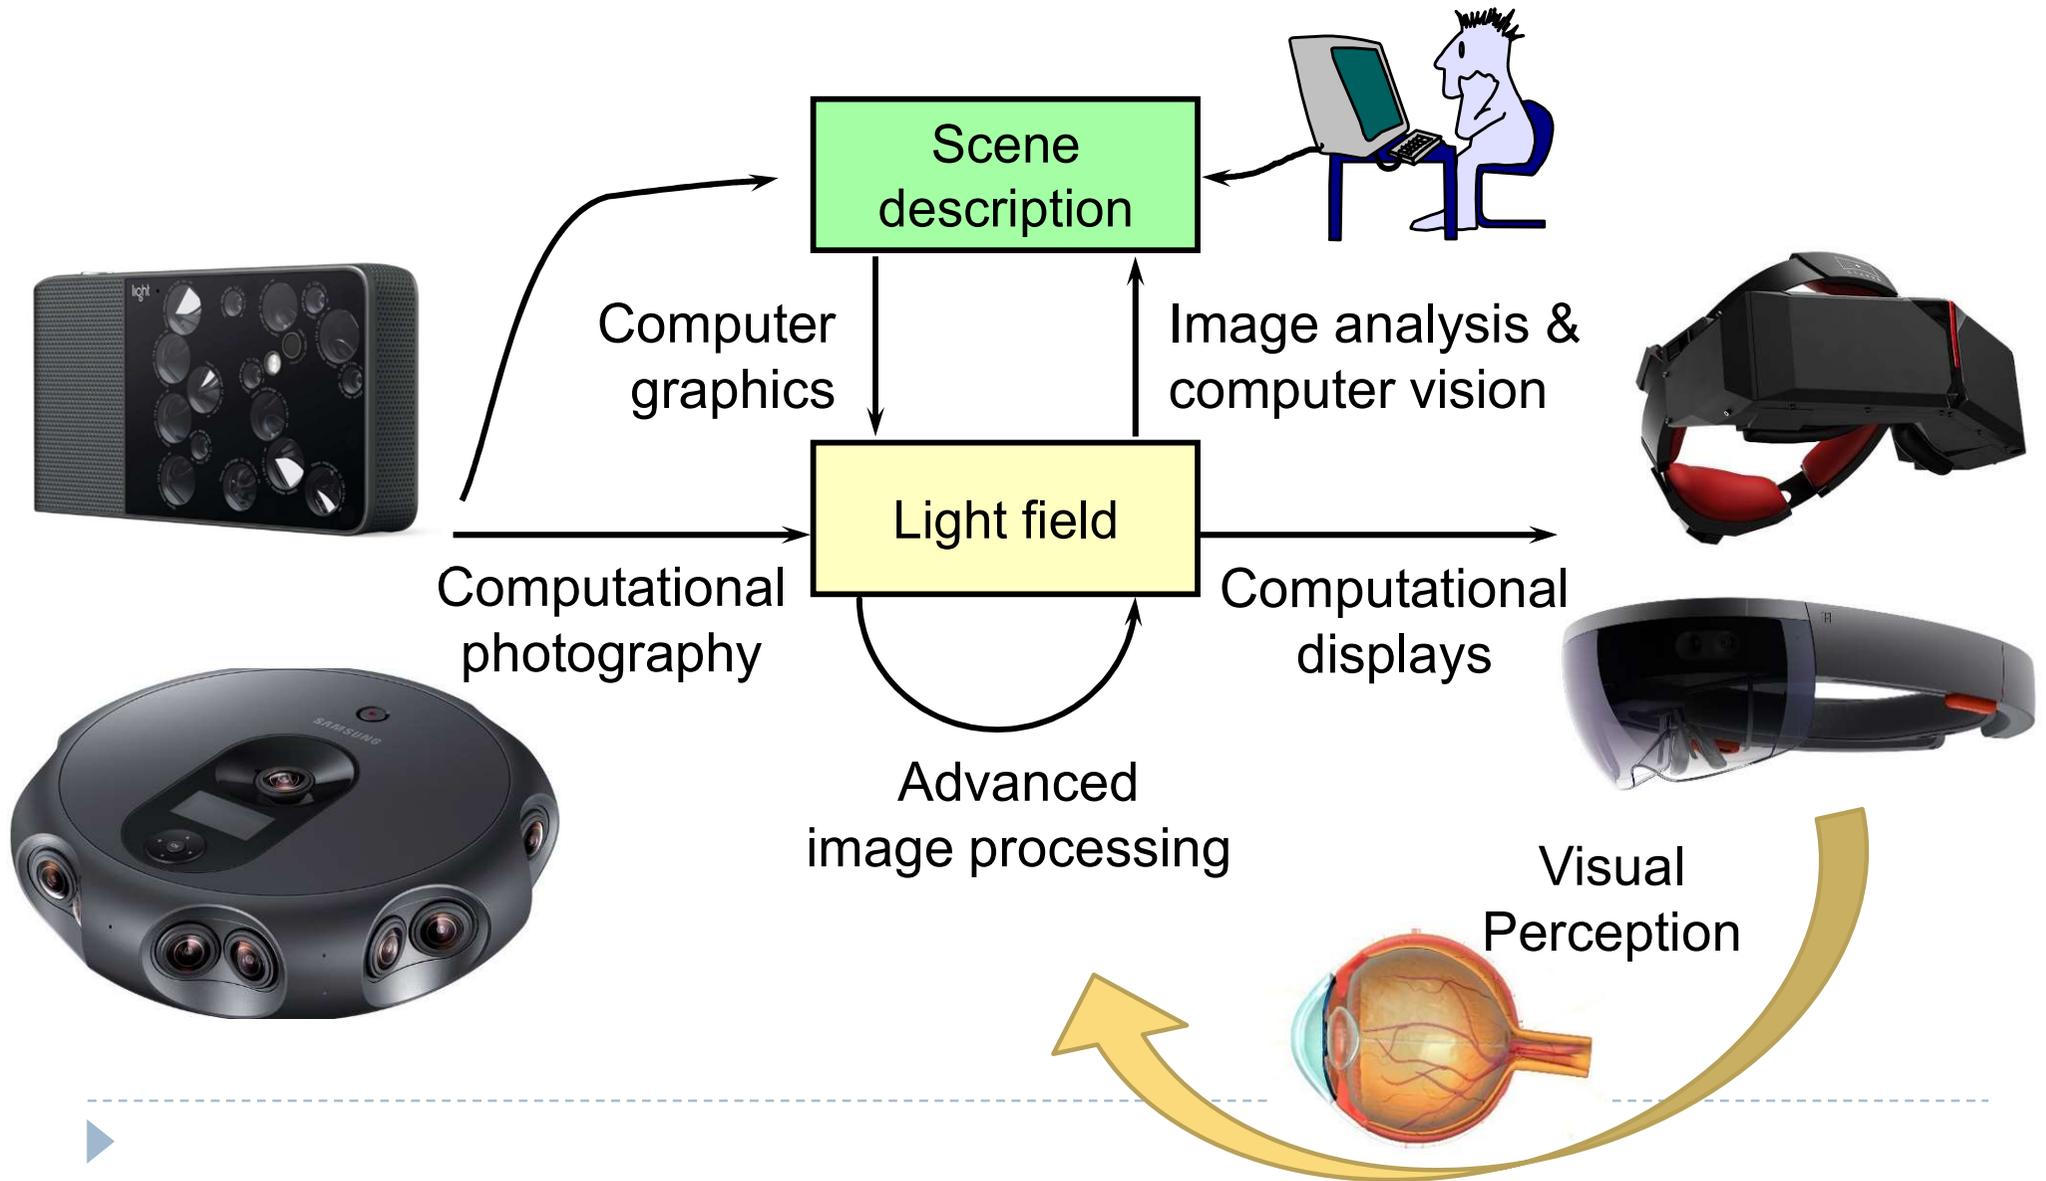

Rafał Mantiuk

Computer Laboratory, University of Cambridge

What are Computer Graphics & Image Processing?

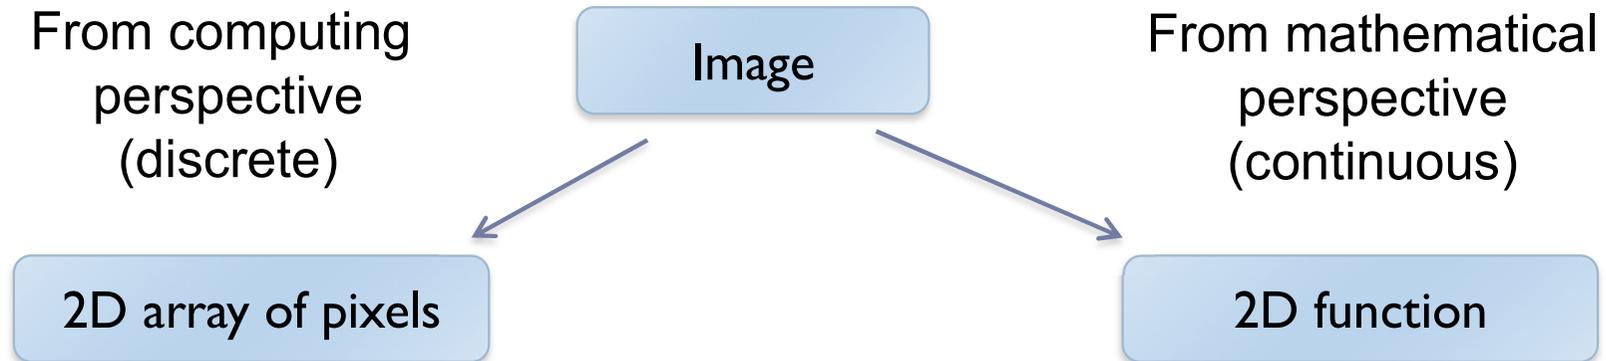

Where are graphics and image processing heading?

What is a (computer) image?

- ▶ A digital photograph? (“JPEG”)
- ▶ A snapshot of real-world lighting?

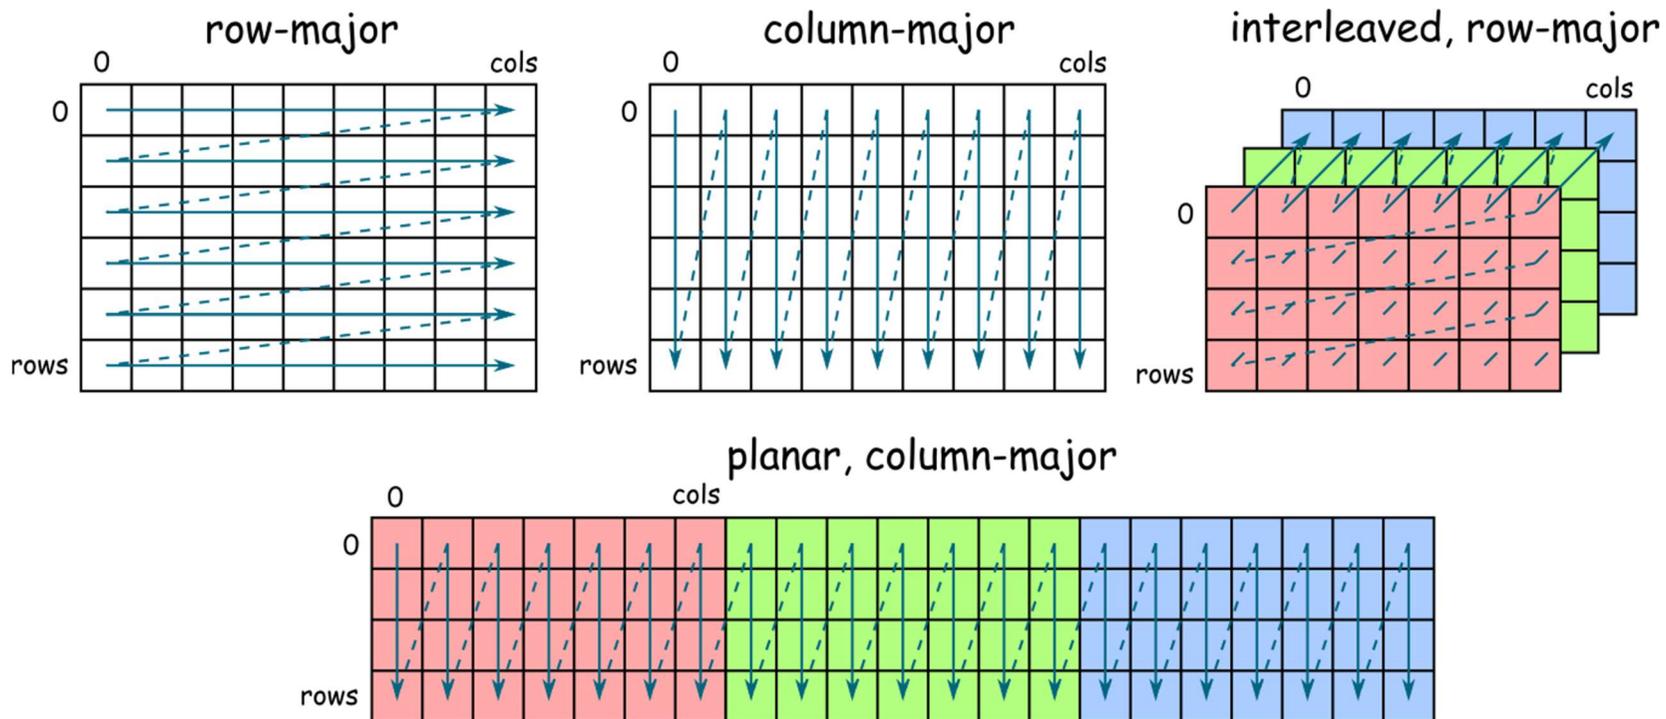

- To represent images in memory
- To create image processing software

- To express image processing as a mathematical problem
- To develop (and understand) algorithms

Image

- ▶ 2D array of pixels
- ▶ In most cases, each pixel takes 3 bytes: one for each red, green and blue
- ▶ But how to store a 2D array in memory?

Stride

- ▶ Calculating the pixel component index in memory

- ▶ For row-major order (grayscale)

$$i(x, y) = x + y \cdot n_{cols}$$

- ▶ For column-major order (grayscale)

$$i(x, y) = x \cdot n_{rows} + y$$

- ▶ For interleaved row-major (colour)

$$i(x, y, c) = x \cdot 3 + y \cdot 3 \cdot n_{cols} + c$$

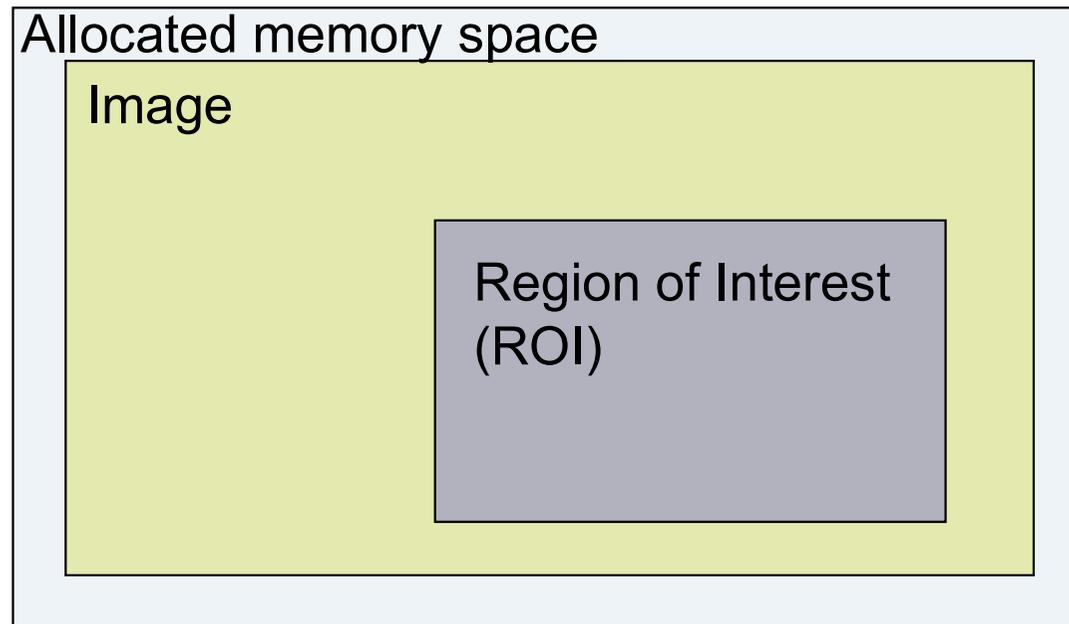

- ▶ General case

$$i(x, y, c) = x \cdot s_x + y \cdot s_y + c \cdot s_c$$

where s_x , s_y and s_c are the strides for the x, y and colour dimensions

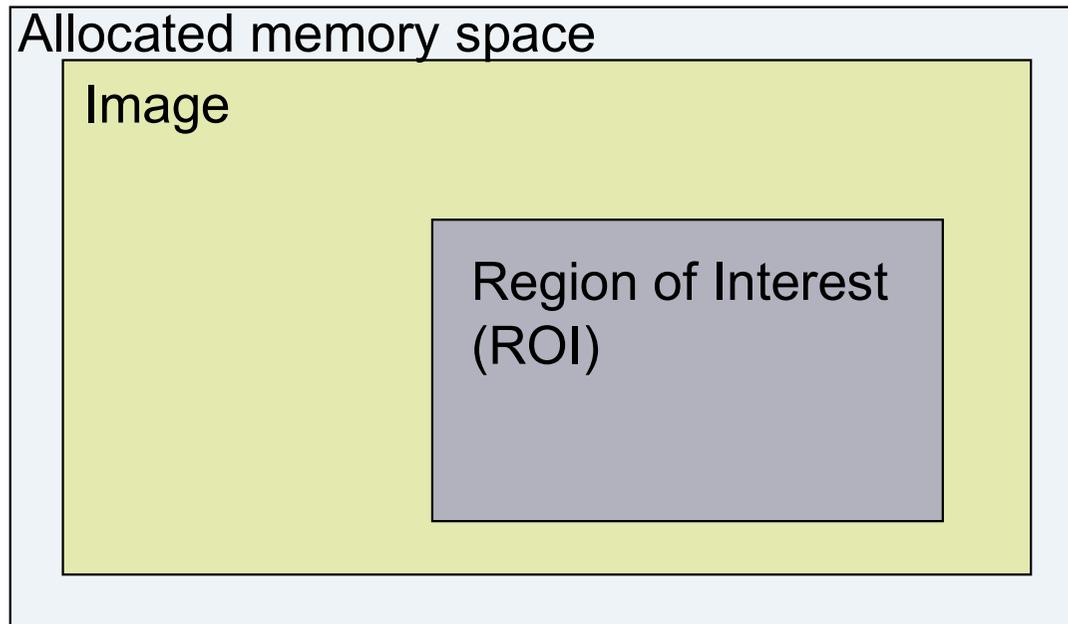

Padded images and stride

- ▶ Sometimes it is desirable to “pad” image with extra pixels
 - ▶ for example when using operators that need to access pixels outside the image border
- ▶ Or to define a region of interest (ROI)

- ▶ How to address pixels for such an image and the ROI?

Padded images and stride

$$i(x, y, c) = i_{first} + x \cdot s_x + y \cdot s_y + c \cdot s_c$$

▶ For row-major, interleaved

- ▶ $s_x = ?$
- ▶ $s_y = ?$
- ▶ $s_c = ?$

Pixel (PIcture ELement)

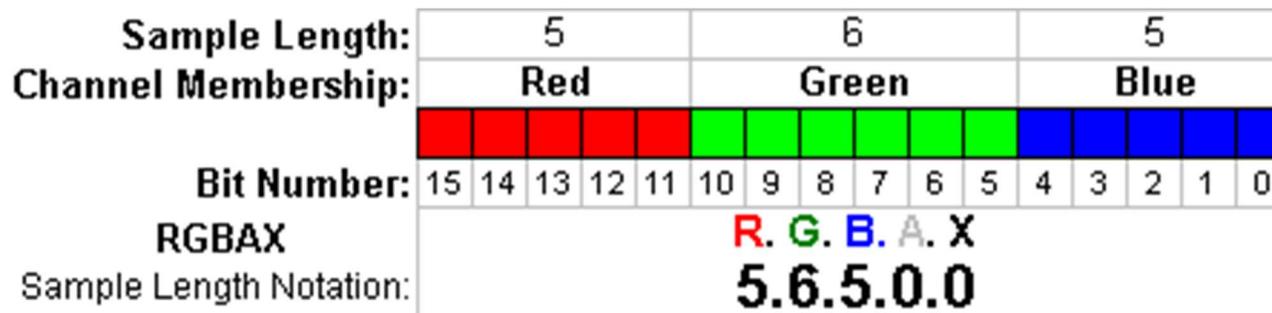

- ▶ Each pixel (usually) consist of three values describing the color

(red, green, blue)

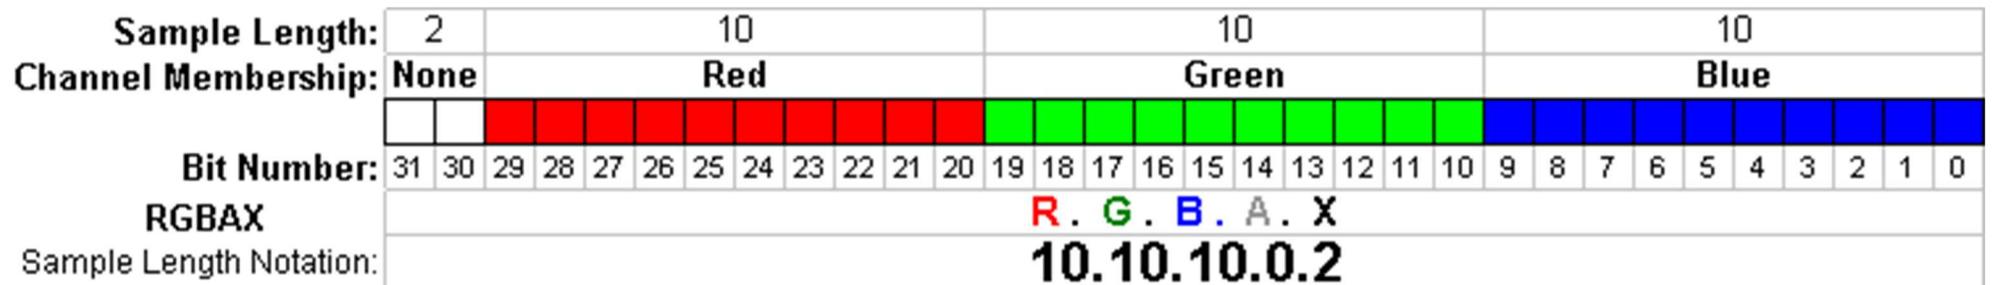

- ▶ For example
 - ▶ (255, 255, 255) for white
 - ▶ (0, 0, 0) for black
 - ▶ (255, 0, 0) for red
- ▶ Why are the values in the 0-255 range?
- ▶ Why red, green and blue? (and not cyan, magenta, yellow)
- ▶ How many bytes are needed to store 5MPixel image? (uncompressed)

Pixel formats, bits per pixel, bit-depth

- ▶ Grayscale – single **color channel**, 8 bits (1 byte)
- ▶ Highcolor – $2^{16}=65,536$ colors (2 bytes)

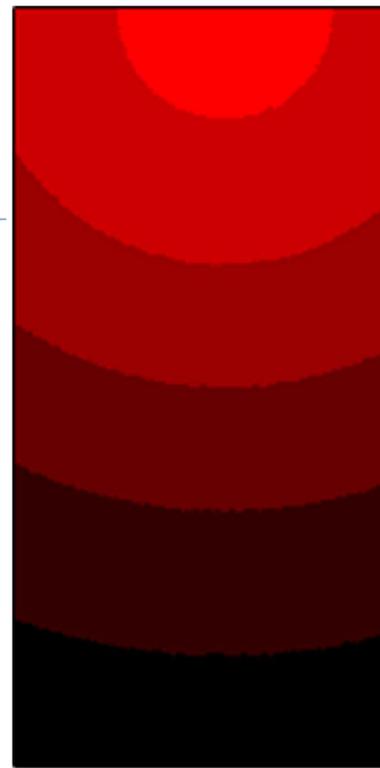

- ▶ Truecolor – $2^{24} = 16,8$ million colors (3 bytes)
- ▶ Deepcolor – even more colors (≥ 4 bytes)

- ▶ But why?

Color banding

- ▶ If there are not enough bits to represent color
- ▶ Looks worse because of the **Mach band** illusion
- ▶ Dithering (added noise) can reduce banding
 - ▶ Printers
 - ▶ Many LCD displays do it too

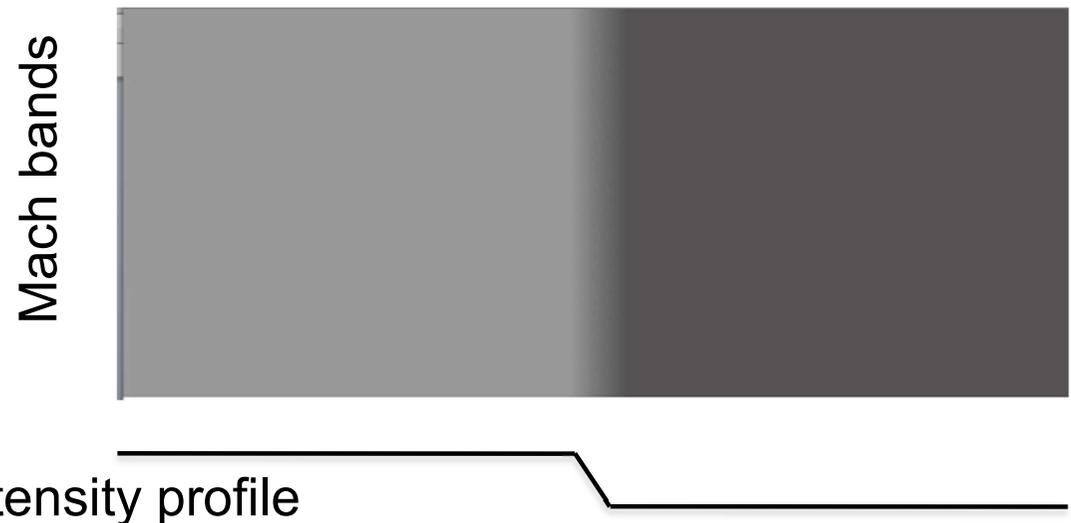

8-bit gradient

8-bit gradient,
dithered

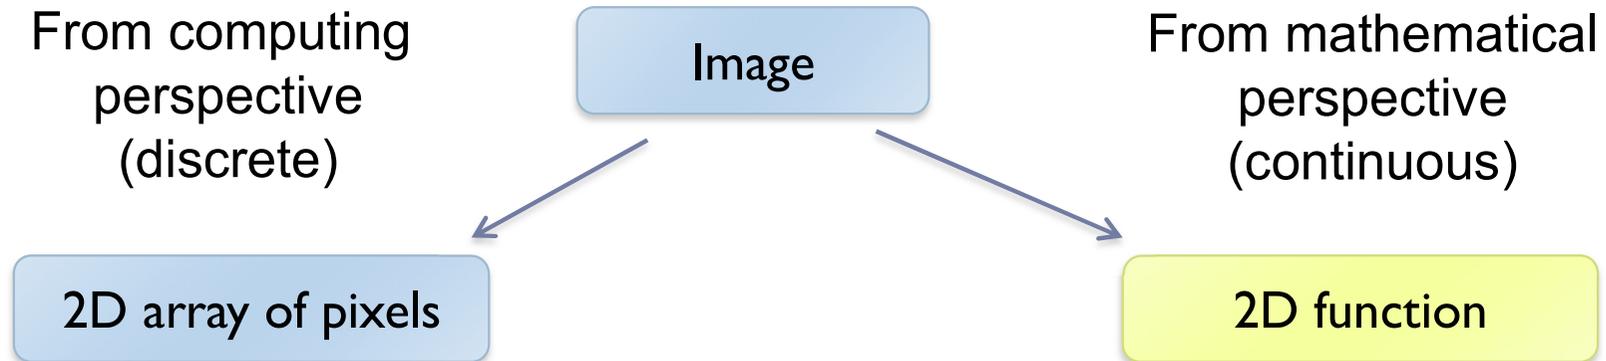

24-bit gradient

What is a (computer) image?

- ▶ A digital photograph? (“JPEG”)
- ▶ A snapshot of real-world lighting?

- To represent images in memory
- To create image processing software

- To express image processing as a mathematical problem
- To develop (and understand) algorithms

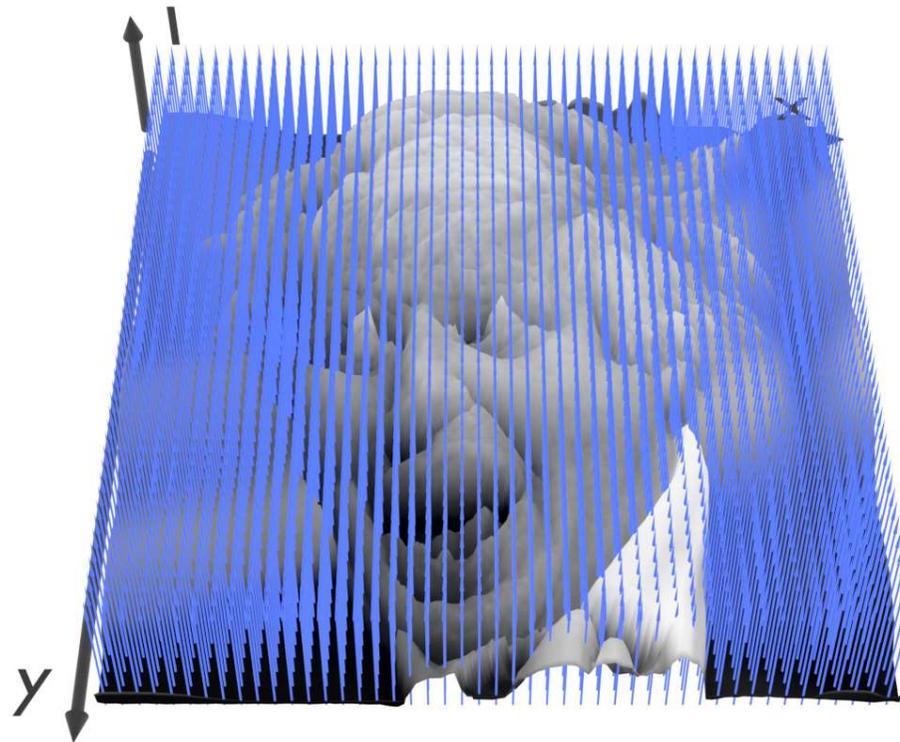

Image – 2D function

- ▶ Image can be seen as a function $I(x,y)$, that gives intensity value for any given coordinate (x,y)

Sampling an image

- ▶ The image can be sampled on a rectangular sampling grid to yield a set of samples. These samples are pixels.

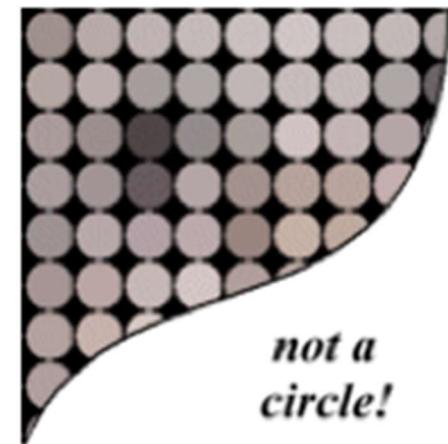

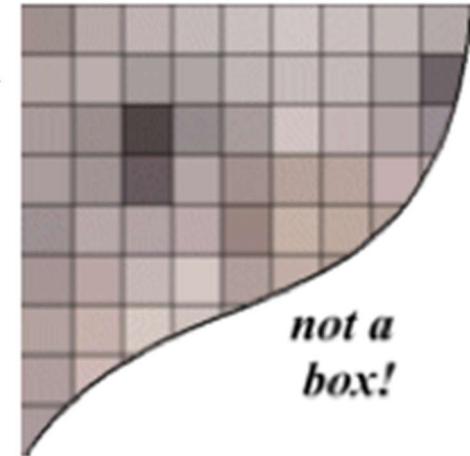

What is a pixel?

- ▶ A pixel is not
 - ▶ a box
 - ▶ a disk
 - ▶ a teeny light

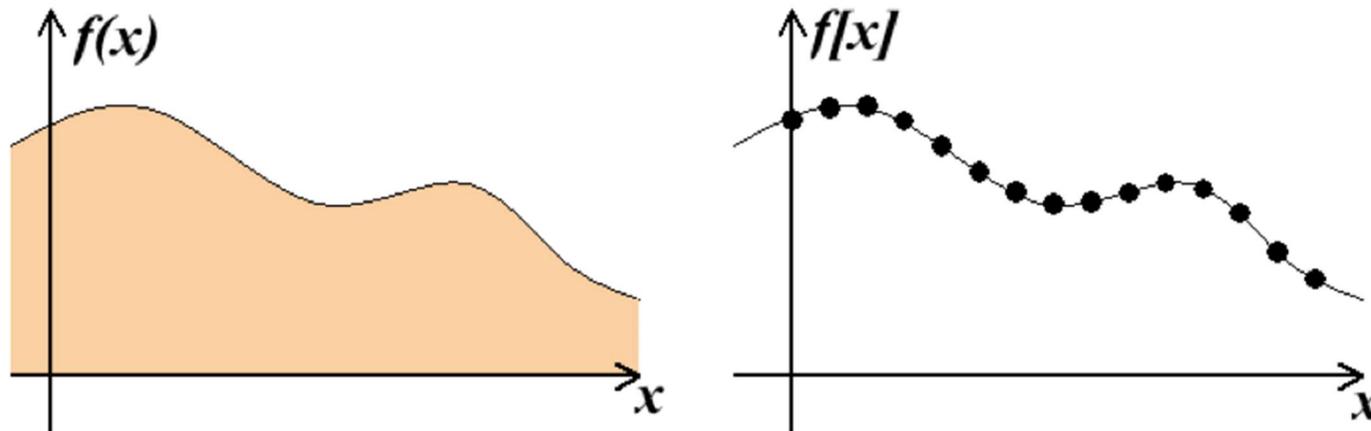

- ▶ A pixel is a point
 - ▶ it has no dimension
 - ▶ it occupies no area
 - ▶ it cannot be seen
 - ▶ it has coordinates

- ▶ A pixel is a **sample**

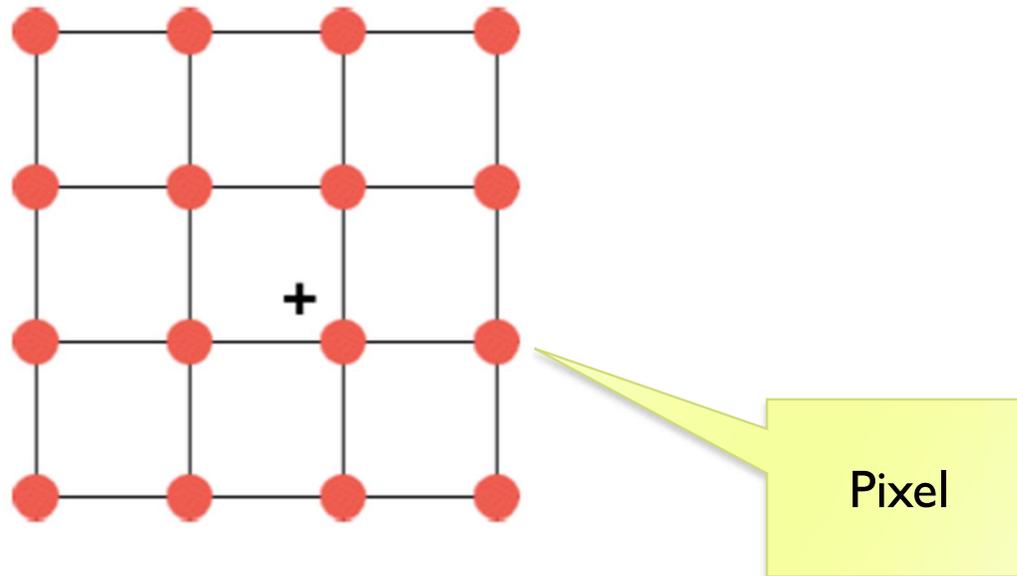

Sampling and quantization

- ▶ The physical world is described in terms of continuous quantities
- ▶ But computers work only with discrete numbers
- ▶ Sampling – process of mapping continuous function to a discrete one
- ▶ Quantization – process of mapping continuous variable to a discrete one

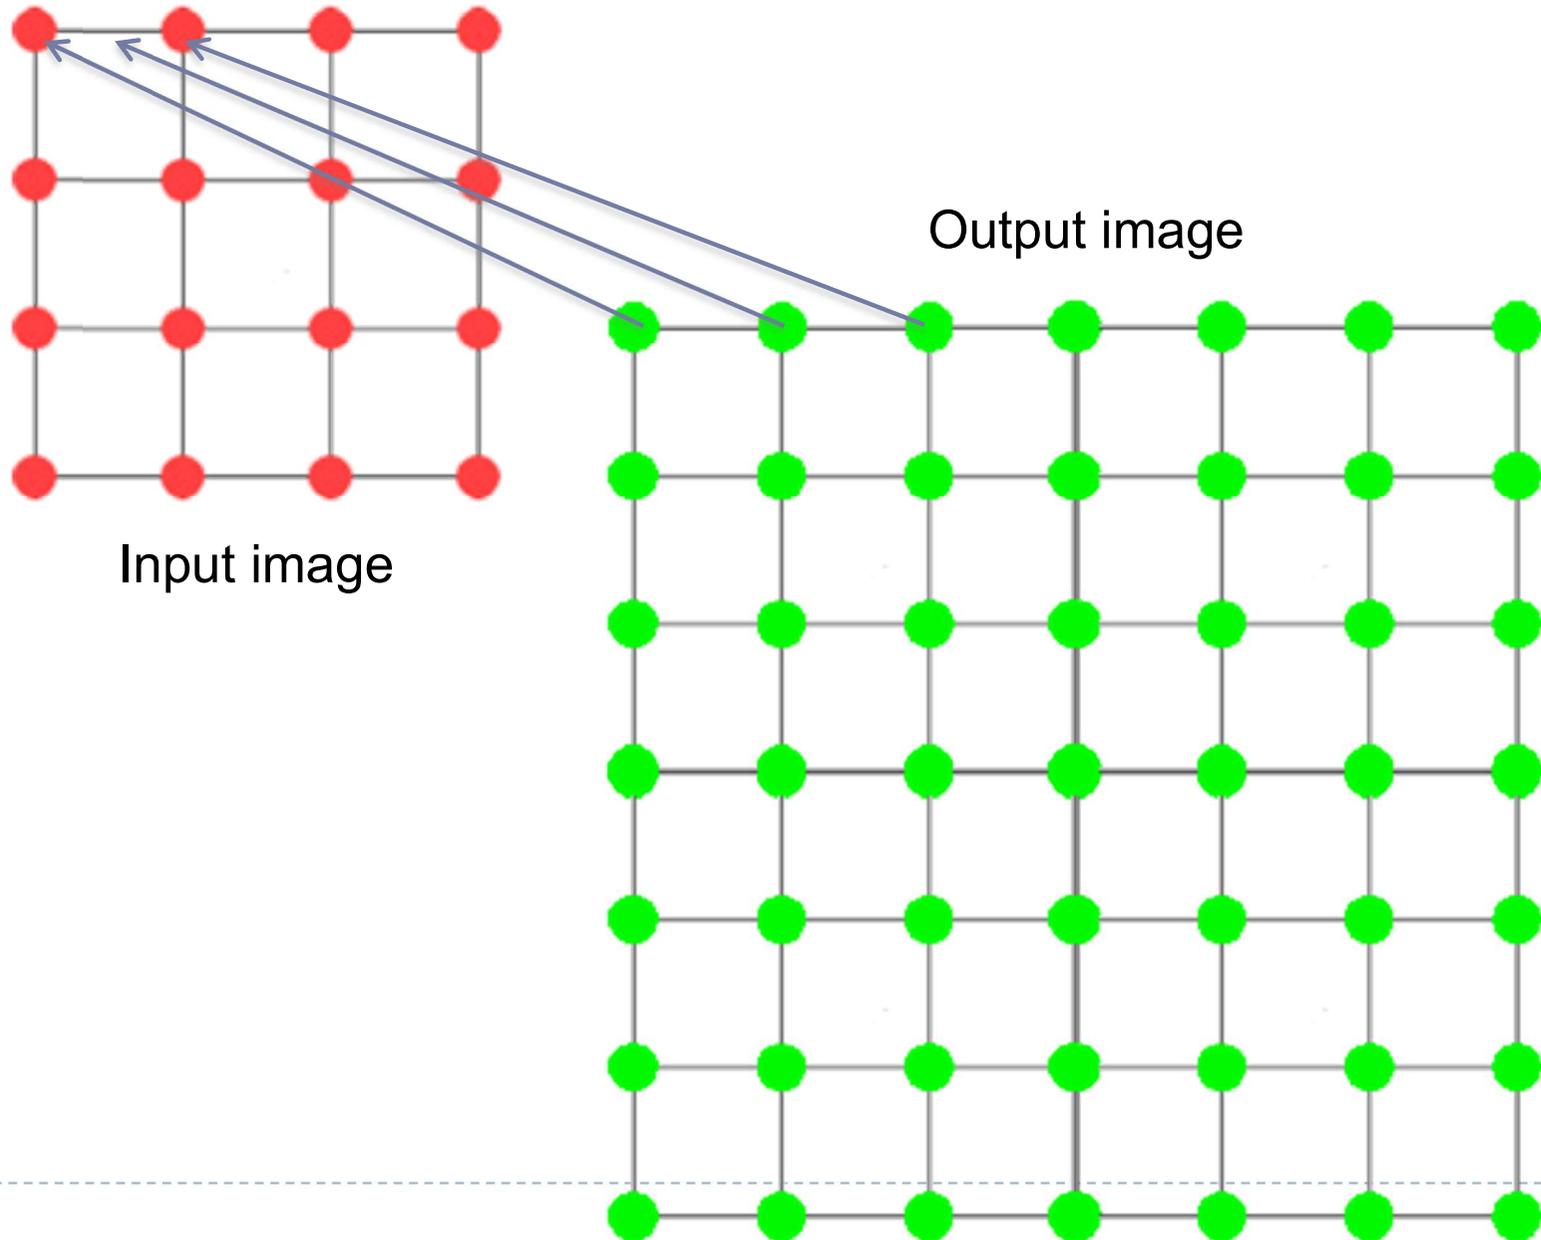

Resampling

- ▶ Some image processing operations require to know the colors that are in-between the original pixels

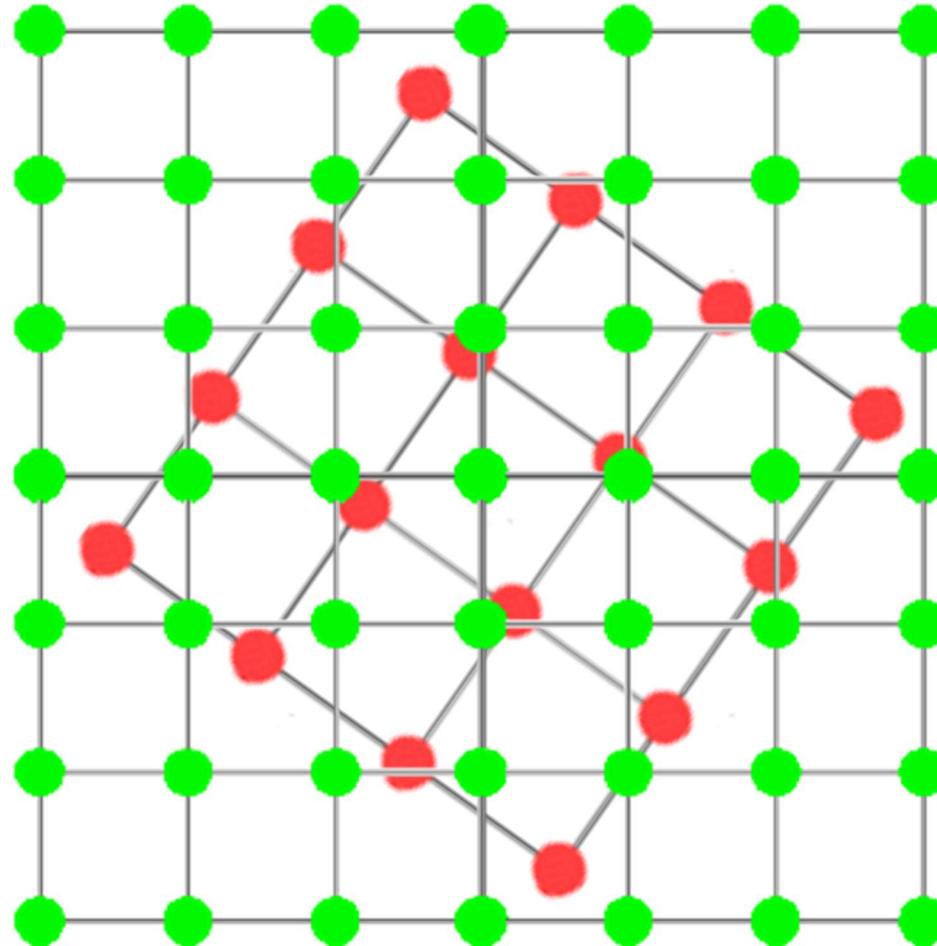

- ▶ What are those operations?
- ▶ How to find these *resampled* pixel values?

Example of resampling: magnification

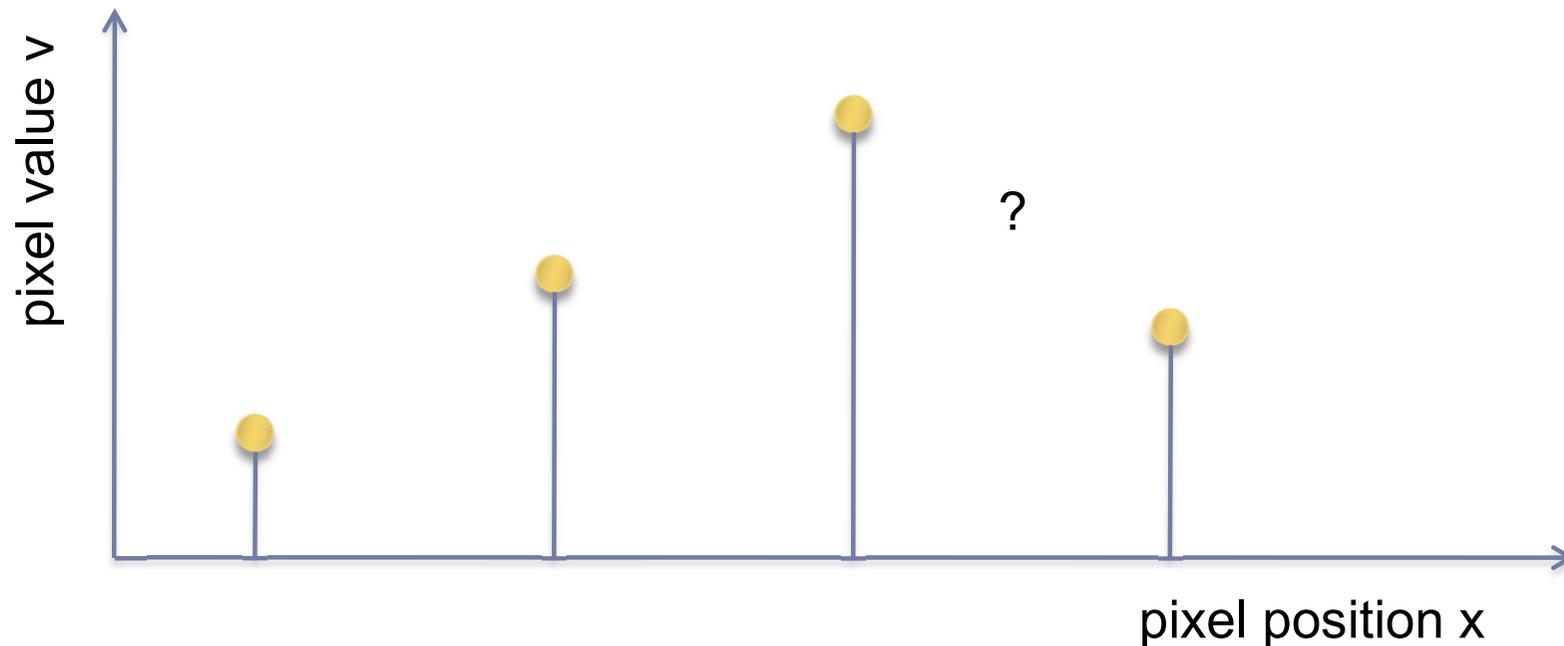

Example of resampling: scaling and rotation

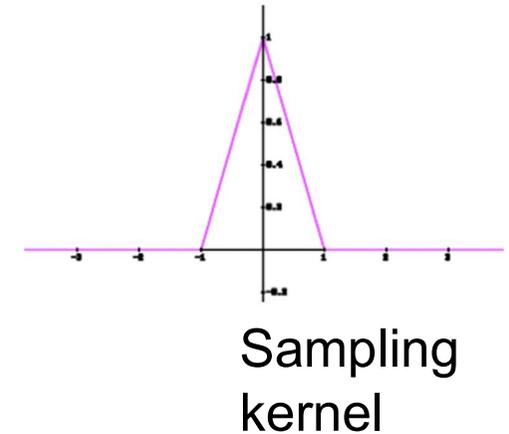

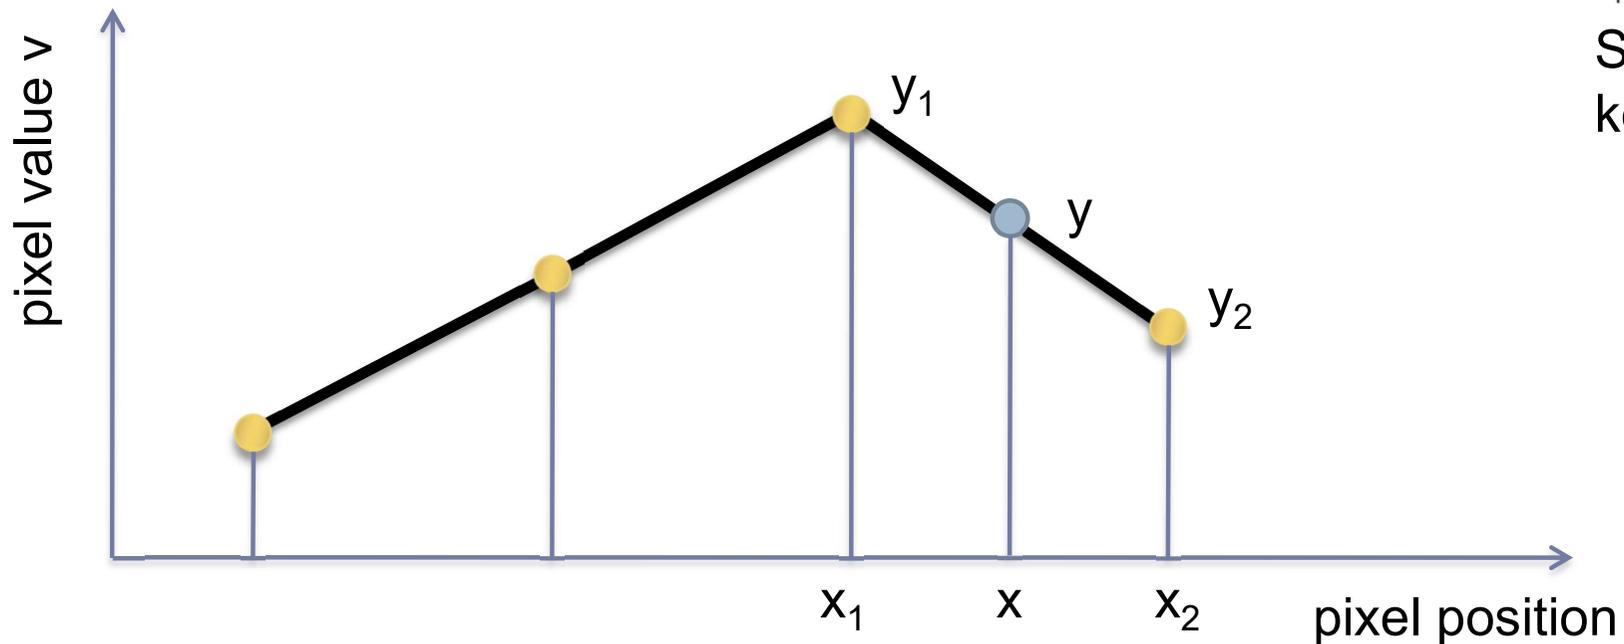

How to resample?

- ▶ In 1D: how to find the most likely resampled pixel value knowing its two neighbors?

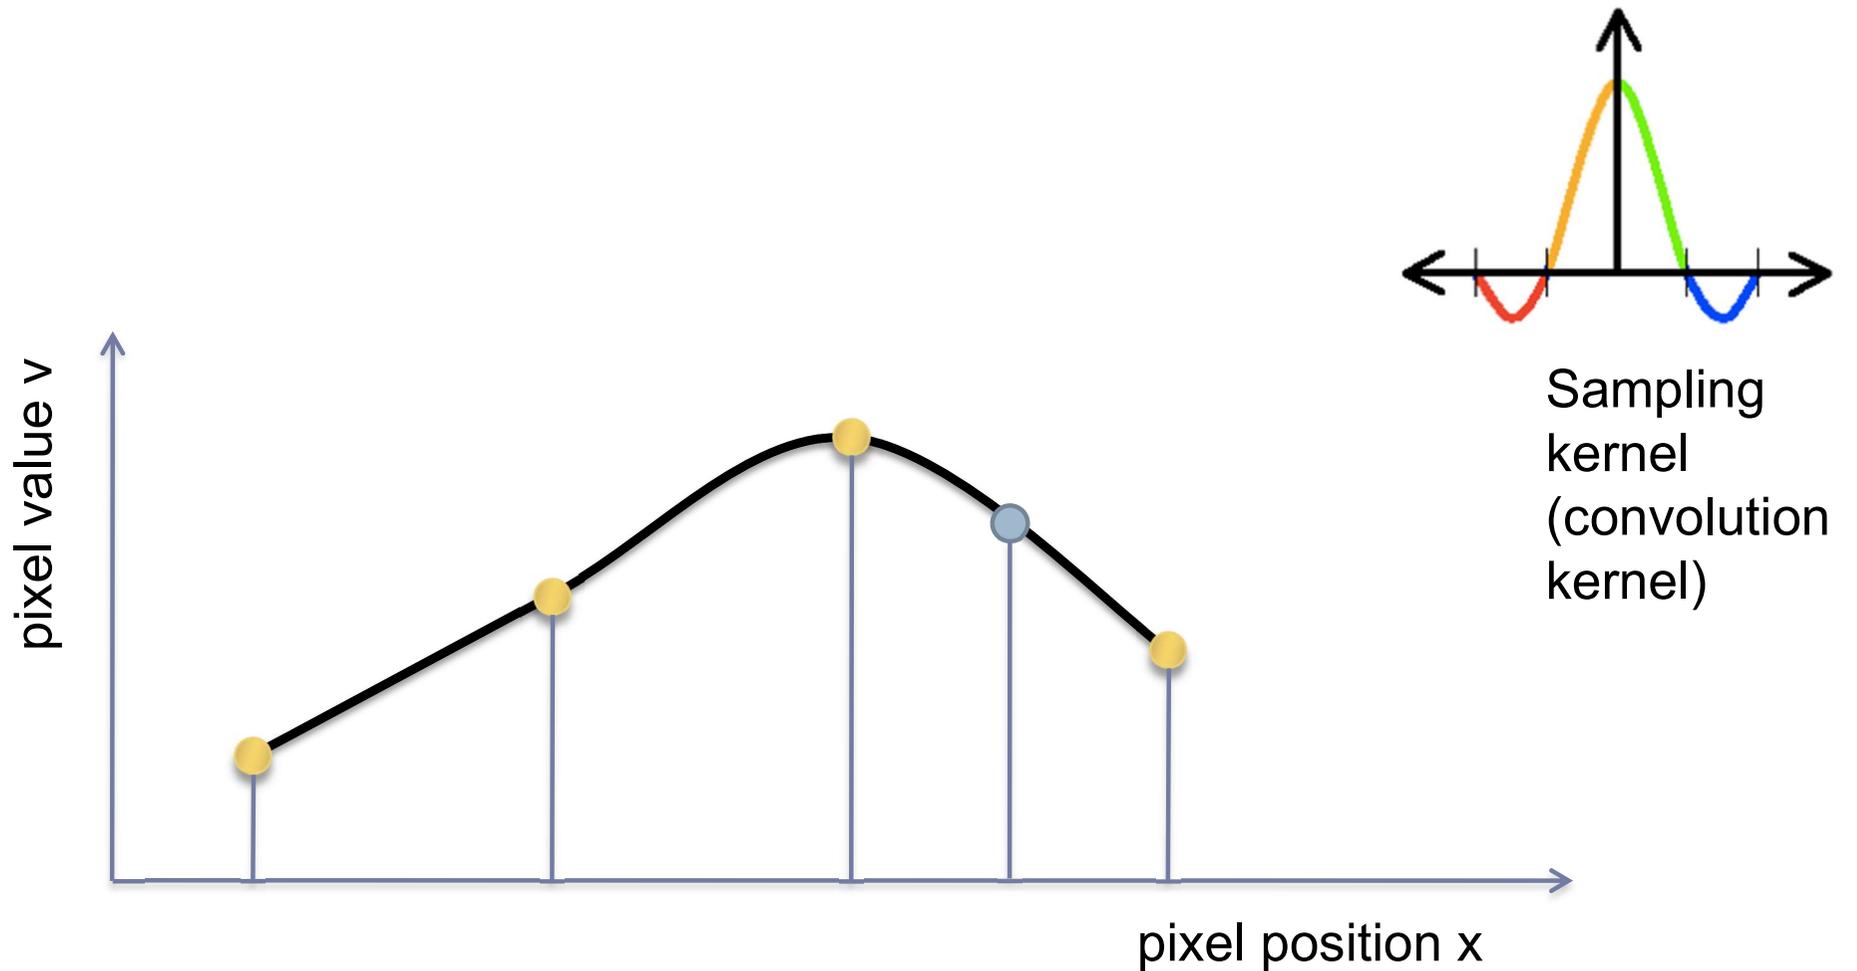

(Bi)Linear interpolation (resampling)

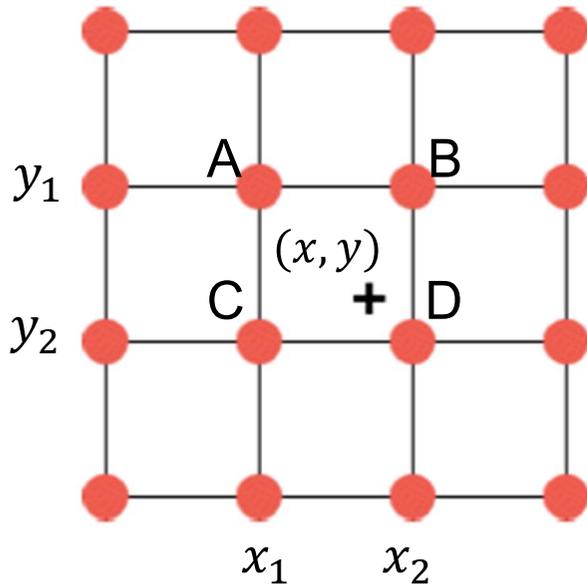

- ▶ Linear – 1D
- ▶ Bilinear – 2D

(Bi)cubic interpolation (resampling)

Bi-linear interpolation

Given the pixel values:

$$I(x_1, y_1) = A$$

$$I(x_2, y_1) = B$$

$$I(x_1, y_2) = C$$

$$I(x_2, y_2) = D$$

Calculate the value of a pixel $I(x, y) = ?$ using bi-linear interpolation.

Hint: Interpolate first between A and B, and between C and D, then interpolate between these two computed values.

Advanced Graphics & Image Processing

Introduction to Image Processing

Part 2/2 – Point ops, filters and pyramids

Rafał Mantiuk

Computer Laboratory, University of Cambridge

Point operators and filters

Blurred

Edge-preserving filter

Original

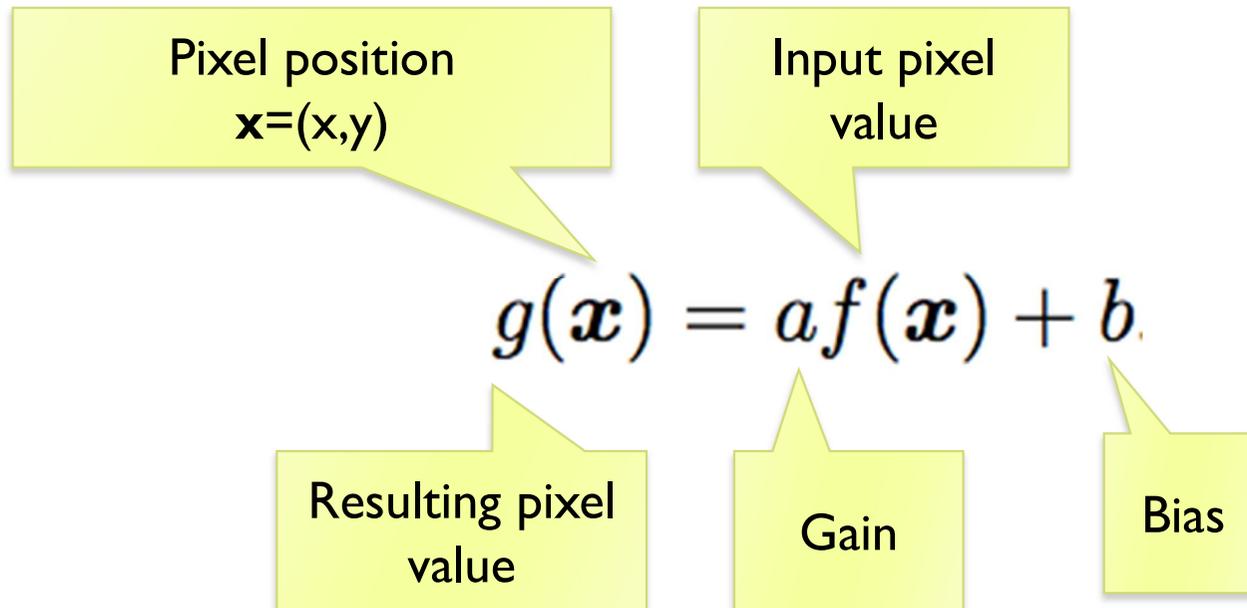

Sharpened

Point operators

- ▶ Modify each pixel independent from one another
- ▶ The simplest case: multiplication and addition

Pixel precision for image processing

- ▶ **Given an RGB image, 8-bit per color channel (uchar)**
 - ▶ What happens if the value of 10 is subtracted from the pixel value of 5 ?
 - ▶ $250 + 10 = ?$
 - ▶ How to multiply pixel values by 1.5 ?
 - ▶ a) Using floating point numbers
 - ▶ b) While avoiding floating point numbers

Image blending

- ▶ Cross-dissolve between two images

The diagram illustrates the cross-dissolve blending equation. It features a central equation $g(\mathbf{x}) = (1 - \alpha)f_0(\mathbf{x}) + \alpha f_1(\mathbf{x})$. Four yellow callout boxes provide context: 'Pixel from image 1' points to $f_0(\mathbf{x})$, 'Pixel from image 2' points to $f_1(\mathbf{x})$, 'Resulting pixel value' points to $g(\mathbf{x})$, and 'Blending parameter' points to α .

$$g(\mathbf{x}) = (1 - \alpha)f_0(\mathbf{x}) + \alpha f_1(\mathbf{x})$$

- ▶ where α is between 0 and 1

Image matting and compositing

- ▶ Matting – the process of extracting an object from the original image
- ▶ Compositing – the process of inserting the object into a different image
- ▶ It is convenient to represent the extracted object as an RGBA image

Transparency, alpha channel

- ▶ **RGBA** – red, green, blue, alpha

- ▶ alpha = 0 – transparent pixel
- ▶ alpha = 1 – opaque pixel

- ▶ **Compositing**

- ▶ Final pixel value:

$$P = \alpha C_{pixel} + (1 - \alpha) C_{background}$$

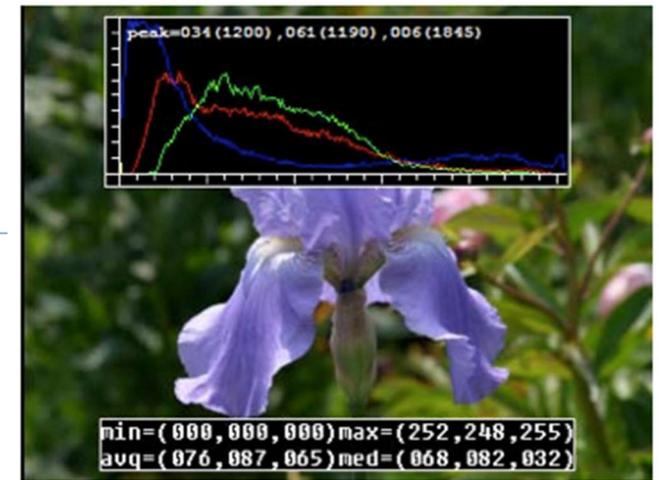

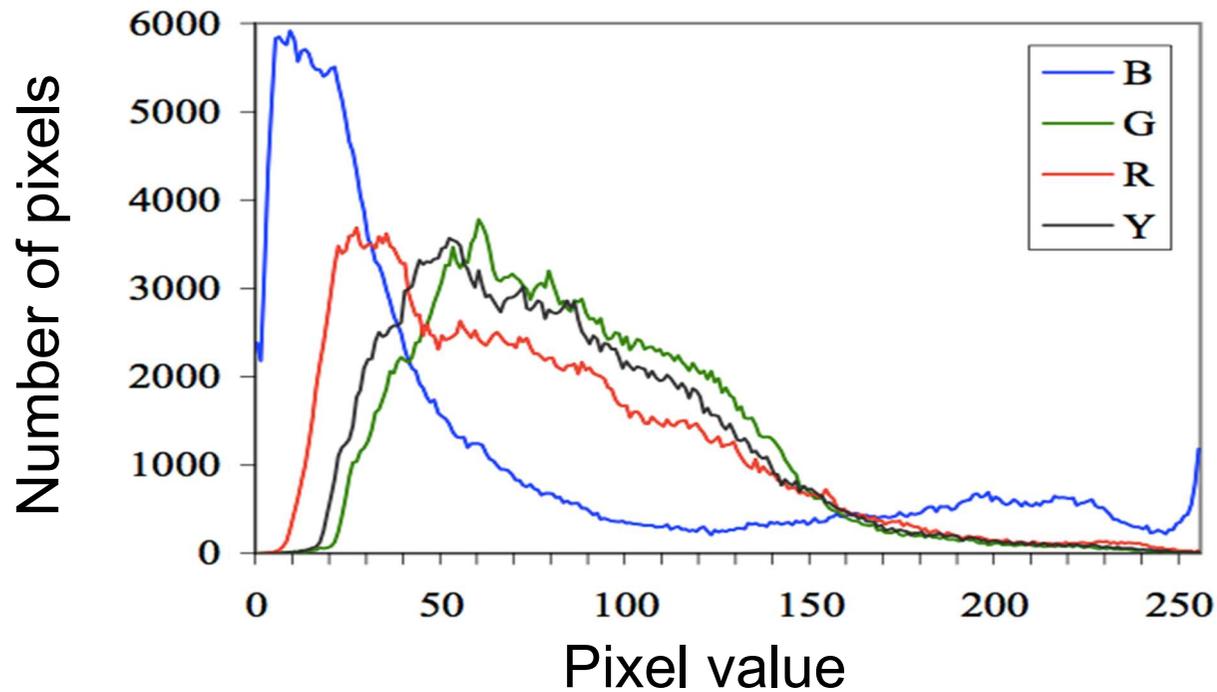

- ▶ Multiple layers:

$$P_0 = C_{background}$$

$$P_i = \alpha_i C_i + (1 - \alpha_i) P_{i-1} \quad i = 1..N$$

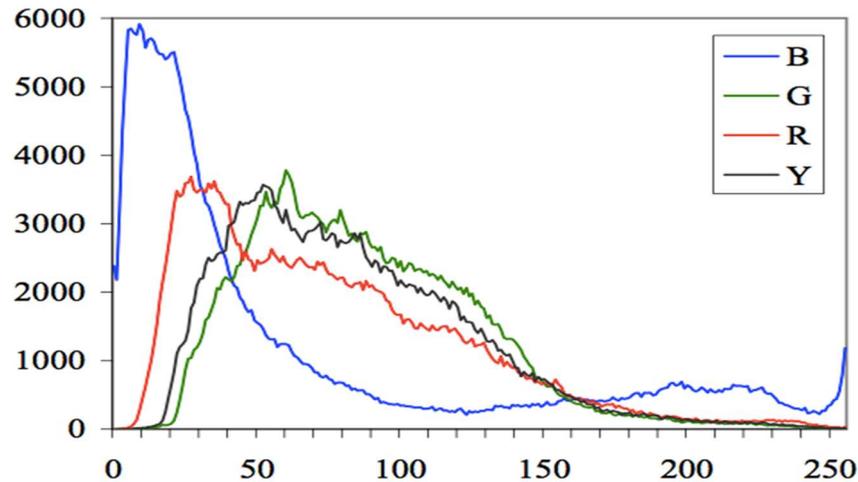

Image histogram

- ▶ histogram / total pixels = probability mass function
 - ▶ what probability does it represent?

Histogram equalization

- ▶ Pixels are non-uniformly distributed across the range of values

- ▶ Would the image look better if we uniformly distribute pixel values (make the histogram more uniform)?
- ▶ How can this be done?

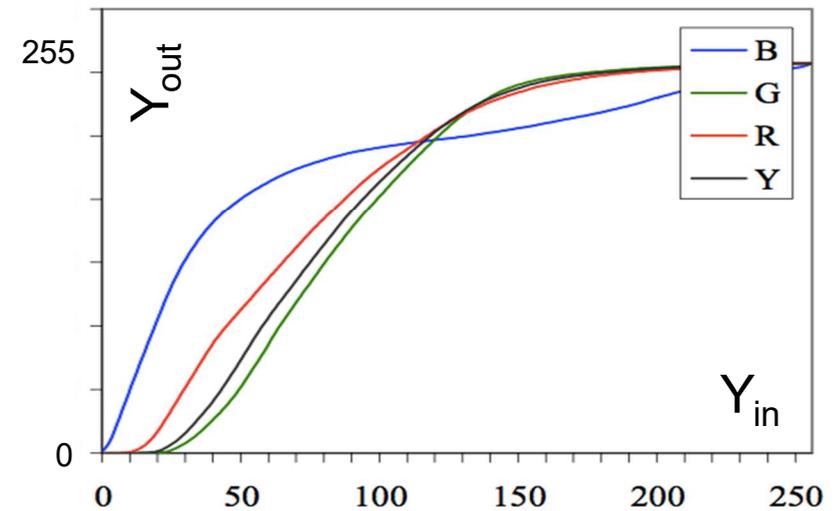

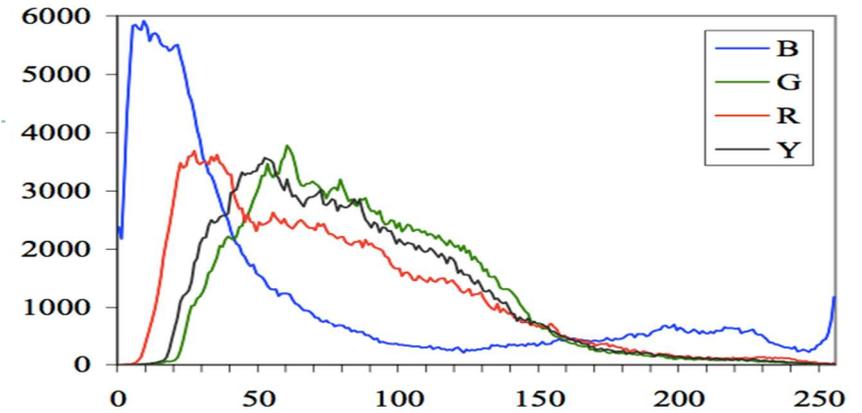

Histogram equalization

- ▶ Step 1: Compute image histogram
- ▶ Step 2: Compute a normalized cumulative histogram

$$c(I) = \frac{1}{N} \sum_{i=0}^I h(i)$$

- ▶ Step 3: Use the cumulative histogram to map pixels to the new values (as a look-up table)

$$Y_{out} = c(Y_{in})$$

Linear filtering

- ▶ Output pixel value is a weighted sum of neighboring pixels

Input pixel value

Kernel (filter)

$$g(i, j) = \sum_{k, l} f(i - k, j - l) h(k, l)$$

Resulting pixel value

Sum over neighboring pixels, e.g. $k=-1, 0, 1, j=-1, 0, 1$ for 3x3 neighborhood

compact notation $g = f * h$

Convolution operation

Linear filter: example

45	60	98	127	132	133	137	133
46	65	98	123	126	128	131	133
47	65	96	115	119	123	135	137
47	63	91	107	113	122	138	134
50	59	80	97	110	123	133	134
49	53	68	83	97	113	128	133
50	50	58	70	84	102	116	126
50	50	52	58	69	86	101	120

$f(x,y)$

*

0.1	0.2	0.1
0.1	0.1	0.1

$h(x,y)$

=

69	95	116	125	129	132
68	92	110	120	126	132
66	86	104	114	124	132
62	78	94	108	120	129
57	69	83	98	112	124
53	60	71	85	100	114

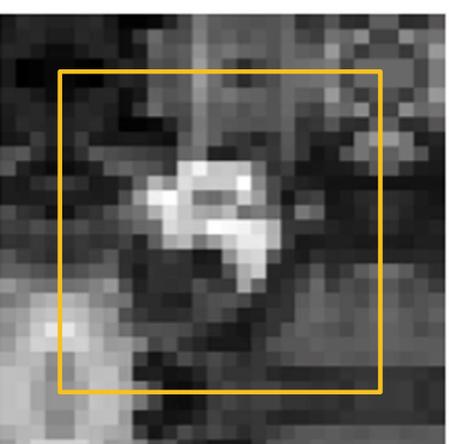

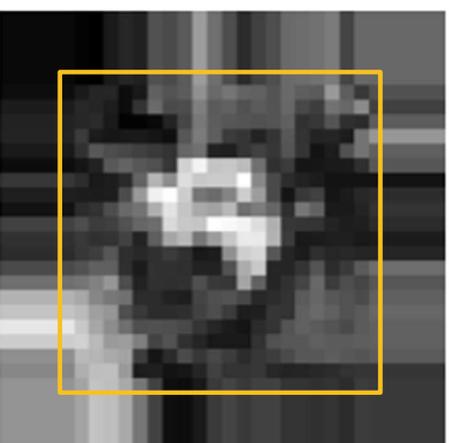

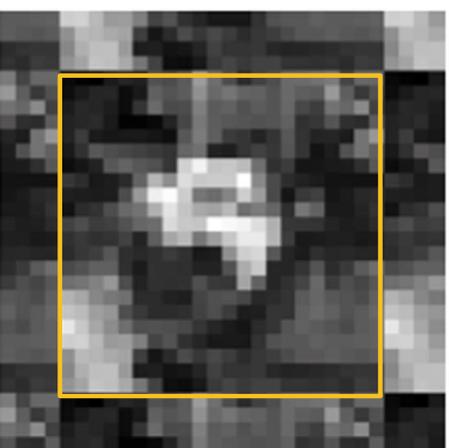

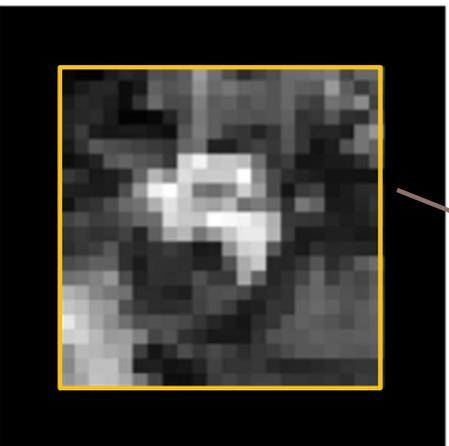

$g(x,y)$

Why is the matrix g smaller than f ?

Padding an image

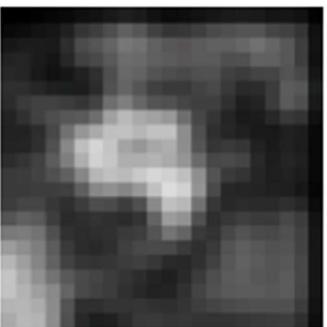

Image edge

Padded image

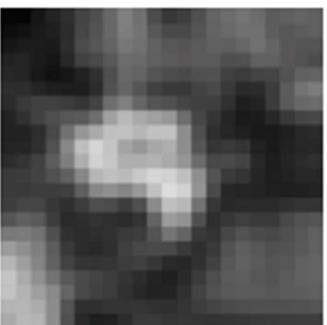

Padded and blurred image

zero

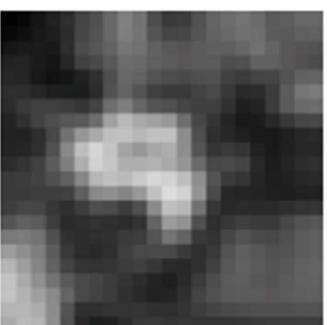

blurred: zero

wrap

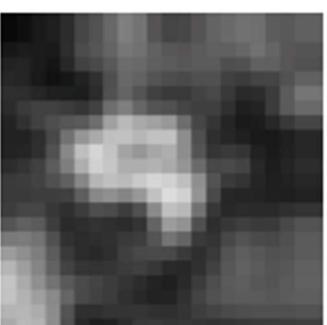

normalized zero

clamp

clamp

mirror

mirror

What is the computational cost of the convolution?

$$g(i, j) = \sum_{k, l} f(i - k, j - l)h(k, l)$$

- ▶ How many multiplications do we need to do to convolve 100x100 image with 9x9 kernel ?
 - ▶ The image is padded, but we do not compute the values for the padded pixels

Separable kernels

- ▶ Convolution operation can be made much faster if split into two separate steps:
 - ▶ 1) convolve all rows in the image with a 1D filter
 - ▶ 2) convolve columns in the result of 1) with another 1D filter
- ▶ But to do this, the kernel must be separable

$$\begin{bmatrix} h_{11} & h_{12} & h_{13} \\ h_{21} & h_{22} & h_{23} \\ h_{31} & h_{32} & h_{33} \end{bmatrix} = \begin{bmatrix} u_1 \\ u_2 \\ u_3 \end{bmatrix} \cdot [v_1 \quad v_2 \quad v_3]$$

$$\vec{h} = \vec{u} \cdot \vec{v}$$

Examples of separable filters

▶ **Box filter:**

$$\begin{bmatrix} \frac{1}{9} & \frac{1}{9} & \frac{1}{9} \\ \frac{1}{9} & \frac{1}{9} & \frac{1}{9} \\ \frac{1}{9} & \frac{1}{9} & \frac{1}{9} \end{bmatrix} = \begin{bmatrix} \frac{1}{3} \\ \frac{1}{3} \\ \frac{1}{3} \end{bmatrix} \cdot \begin{bmatrix} \frac{1}{3} & \frac{1}{3} & \frac{1}{3} \end{bmatrix}$$

▶ **Gaussian filter:**

$$G(x, y; \sigma) = \frac{1}{2\pi\sigma^2} e^{-\frac{x^2+y^2}{2\sigma^2}}$$

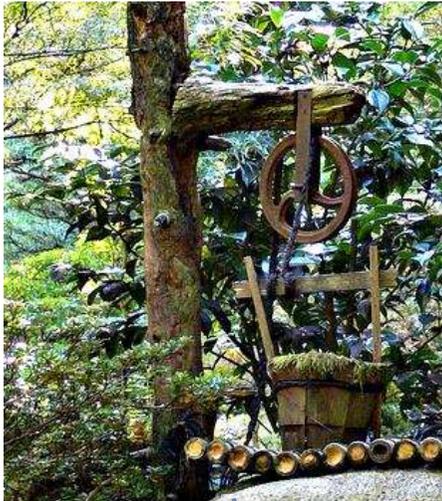

▶ What are the corresponding 1D components of this separable filter ($u(x)$ and $v(y)$)?

$$G(x, y) = u(x) \cdot v(y)$$

Unsharp masking

- ▶ How to use blurring to sharpen an image ?

results

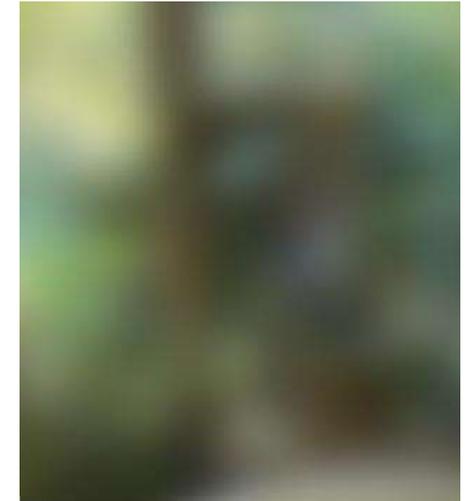

original image

high-pass image

blurry image

$$g_{\text{sharp}} = f + \gamma(f - h_{\text{blur}} * f)$$

Diagrammatic annotations: Arrows point from the 'results' image to the g_{sharp} term, from the 'original image' to the f term, from the 'high-pass image' to the $(f - h_{\text{blur}} * f)$ term, and from the 'blurry image' to the $h_{\text{blur}} * f$ term. Brackets are used to group the terms in the equation.

Why “linear” filters ?

- ▶ Linear functions have two properties:
 - ▶ Additivity: $f(x) + f(y) = f(x + y)$
 - ▶ Homogeneity: $f(ax) = af(x)$ (where “ f ” is a linear function)
- ▶ Why is it important?
 - ▶ Linear operations can be performed in an arbitrary order
$$\text{blur}(aF + b) = a \text{blur}(F) + b$$
 - ▶ Linearity of the Gaussian filter could be used to improve the performance of your image processing operation
 - ▶ This is also how separable filters work:

Matrix multiplication

Convolution

The components
of a separable
kernel

$$(u \cdot v) * f = u * (v * f)$$

An image

Operations on binary images

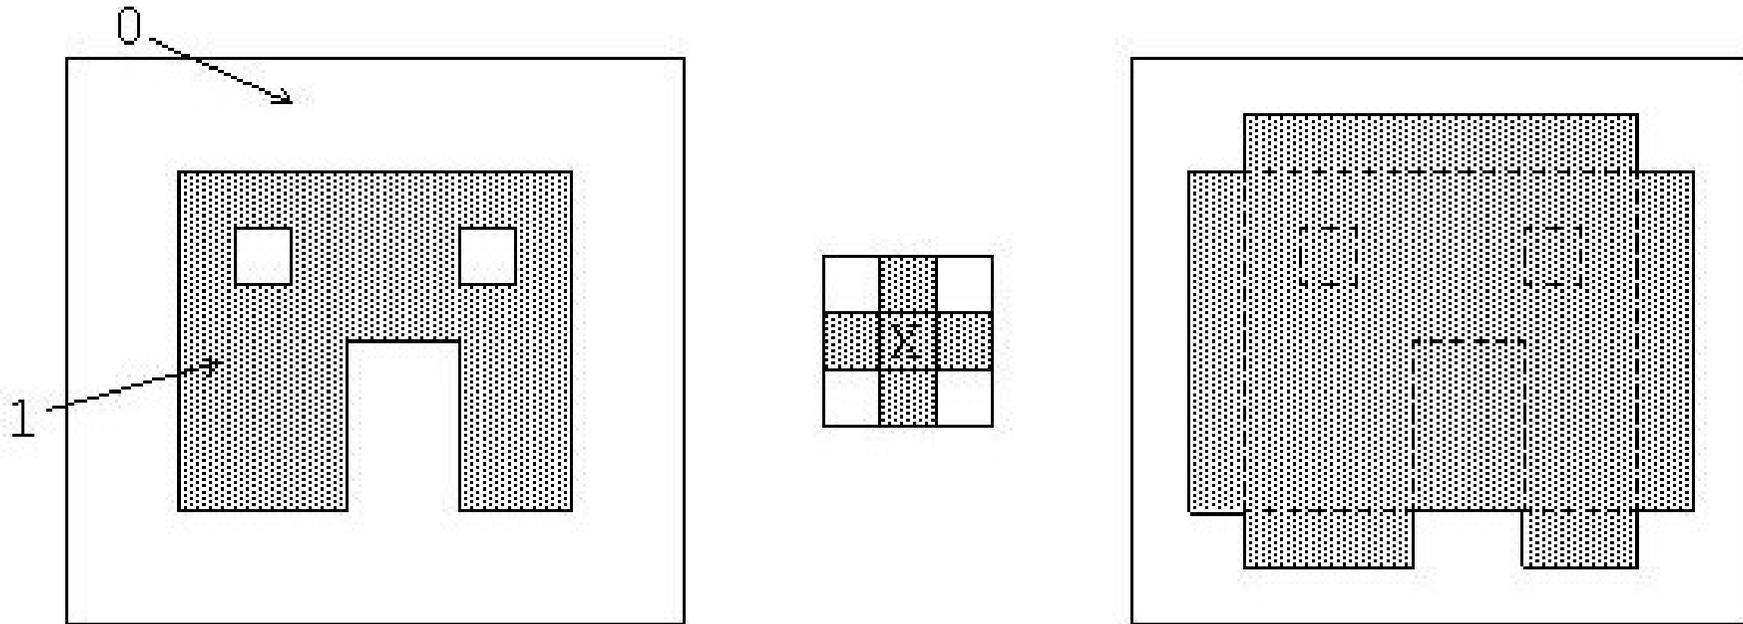

- ▶ Essential for many computer vision tasks

- ▶ Binary image can be constructed by thresholding a grayscale image

$$\theta(f, c) = \begin{cases} 1 & \text{if } f \geq c, \\ 0 & \text{else,} \end{cases}$$

Morphological filters: dilation

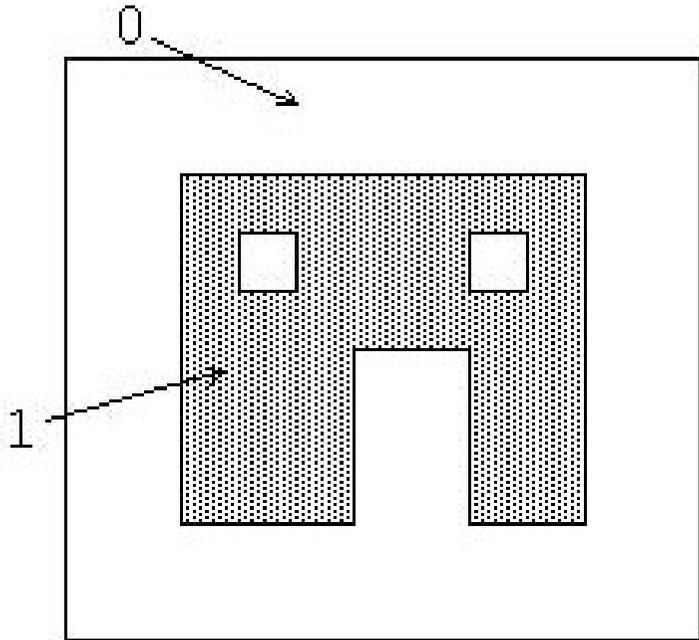

a) Original image

b) Structuring element;
x = origin

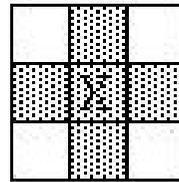

c) Image after dilation;
original in dashes

- ▶ Set the pixel to the maximum value of the neighboring pixels within the structuring element
- ▶ What could it be useful for ?

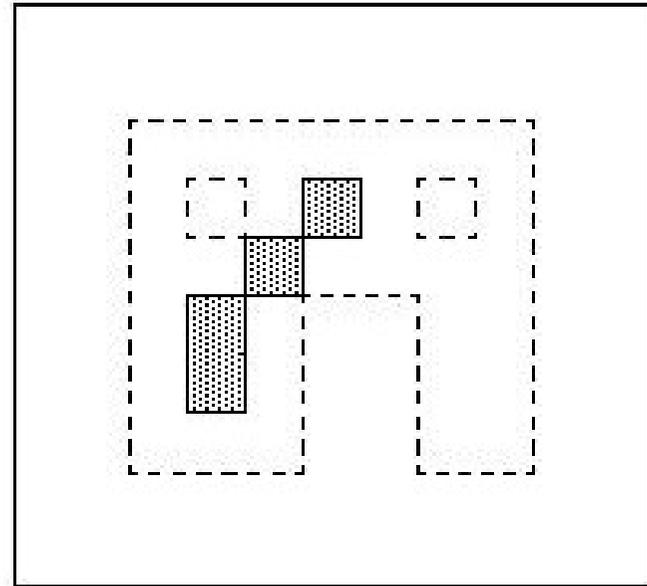

Morphological filters: erosion

a) Original image

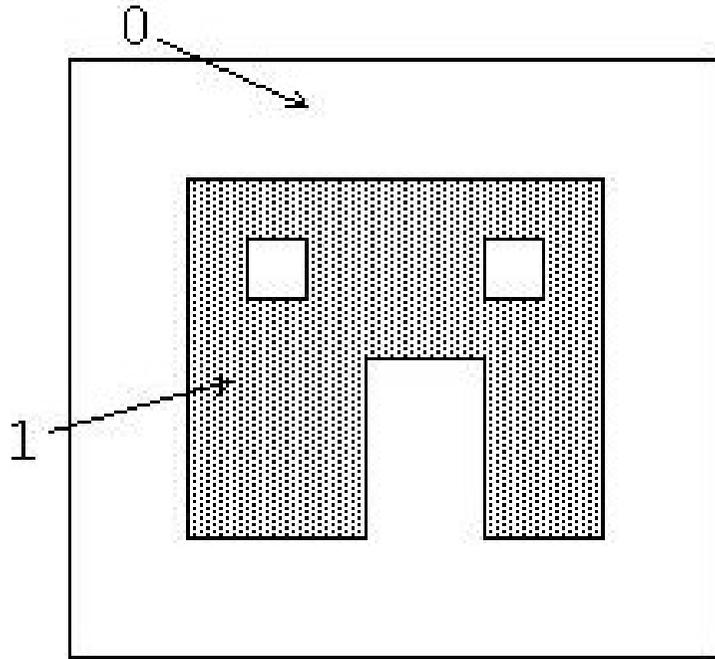

b) Structuring element;
x = origin

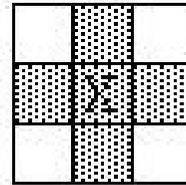

c) Image after erosion;
original in dashes

- ▶ Set the value to the minimum value of all the neighboring pixels within the structuring element
- ▶ What could it be useful for ?

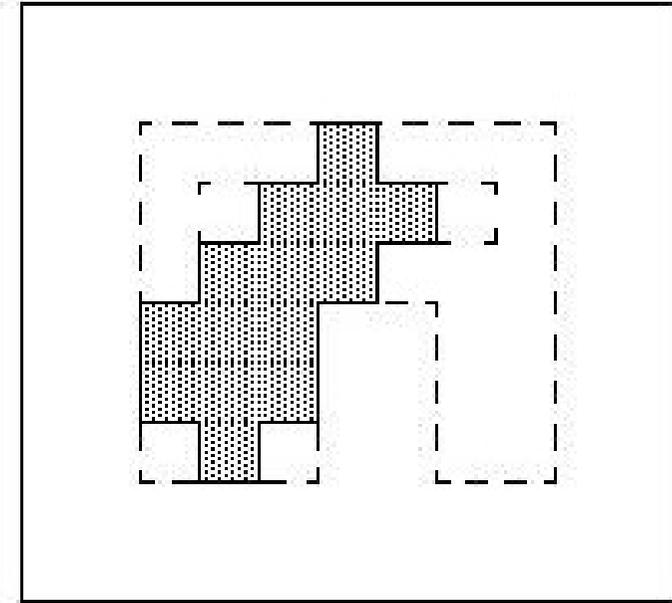

Morphological filters: opening

a) Original image

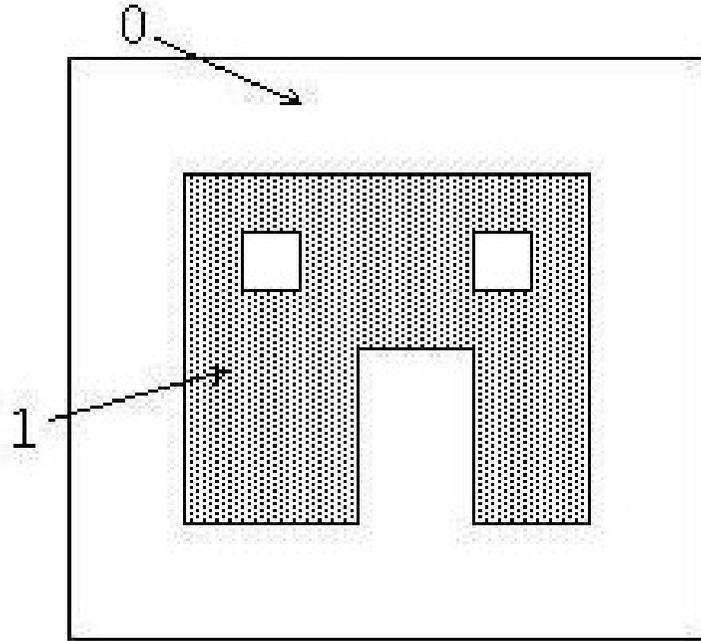

b) Structuring element;
x = origin

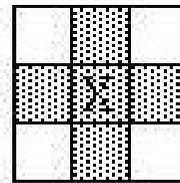

c) Image after opening =
erosion followed by
dilation

- ▶ Erosion followed by dilation
- ▶ What could it be useful for?

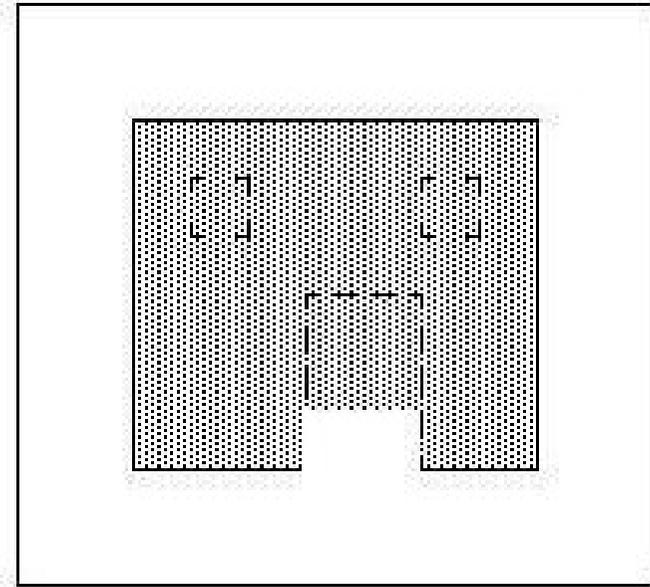

Morphological filters: closing

a) Original image

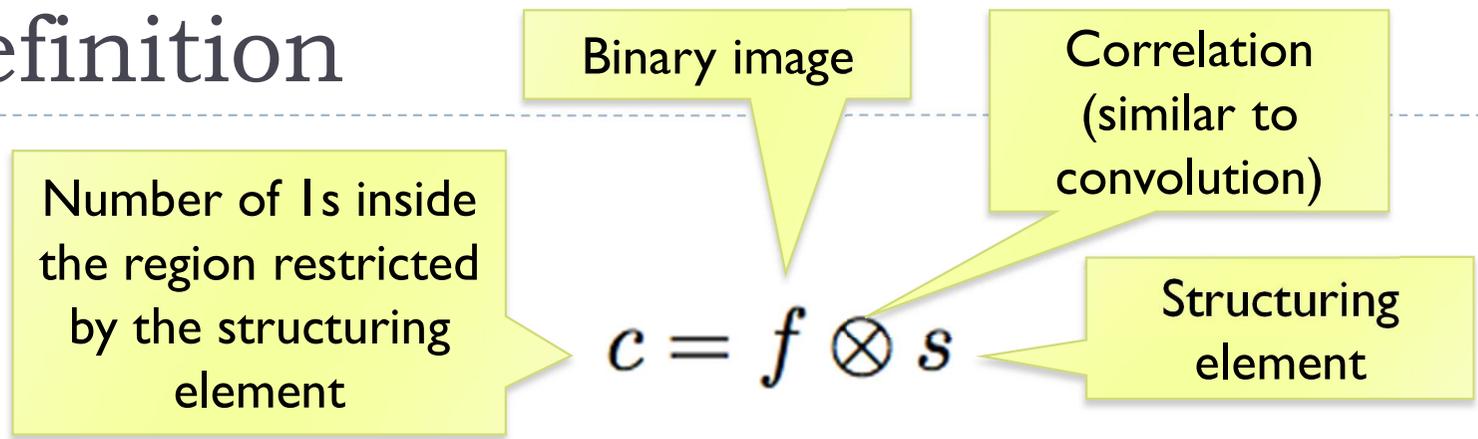

b) Structuring element;
 x = origin

c) Image after closing =
dilation followed by
erosion; original in
dashes.

- ▶ Dilation followed by erosion
- ▶ What could it be useful for ?

Binary morphological filters: formal definition

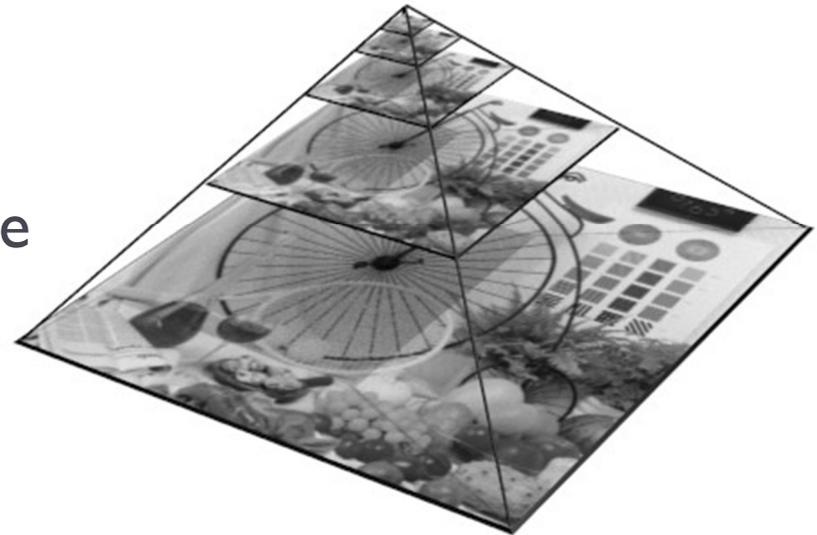

S – size of structuring element (number of 1s in the SI)

- **dilation:** $\text{dilate}(f, s) = \theta(c, 1)$;
 - **erosion:** $\text{erode}(f, s) = \theta(c, S)$;
 - **majority:** $\text{maj}(f, s) = \theta(c, S/2)$;
 - **opening:** $\text{open}(f, s) = \text{dilate}(\text{erode}(f, s), s)$;
 - **closing:** $\text{close}(f, s) = \text{erode}(\text{dilate}(f, s), s)$.
- $$\theta(f, c) = \begin{cases} 1 & \text{if } f \geq c, \\ 0 & \text{else,} \end{cases}$$

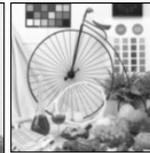

Multi-scale image processing (pyramids)

- ▶ Multi-scale processing operates on an image represented at several sizes (scales)
 - ▶ Fine level for operating on small details
 - ▶ Coarse level for operating on large features
- ▶ Example:
 - ▶ Motion estimation
 - ▶ Use fine scales for objects moving slowly
 - ▶ Use coarse scale for objects moving fast
 - ▶ Blending (to avoid sharp boundaries)

Two types of pyramids

input

Bilateral filter

Input image

$$y(\mathbf{p}) = \frac{\sum_{\mathbf{q} \in \Omega} x(\mathbf{q}) w(\mathbf{p}, \mathbf{q})}{\sum_{\mathbf{q} \in \Omega} w(\mathbf{p}, \mathbf{q})}$$

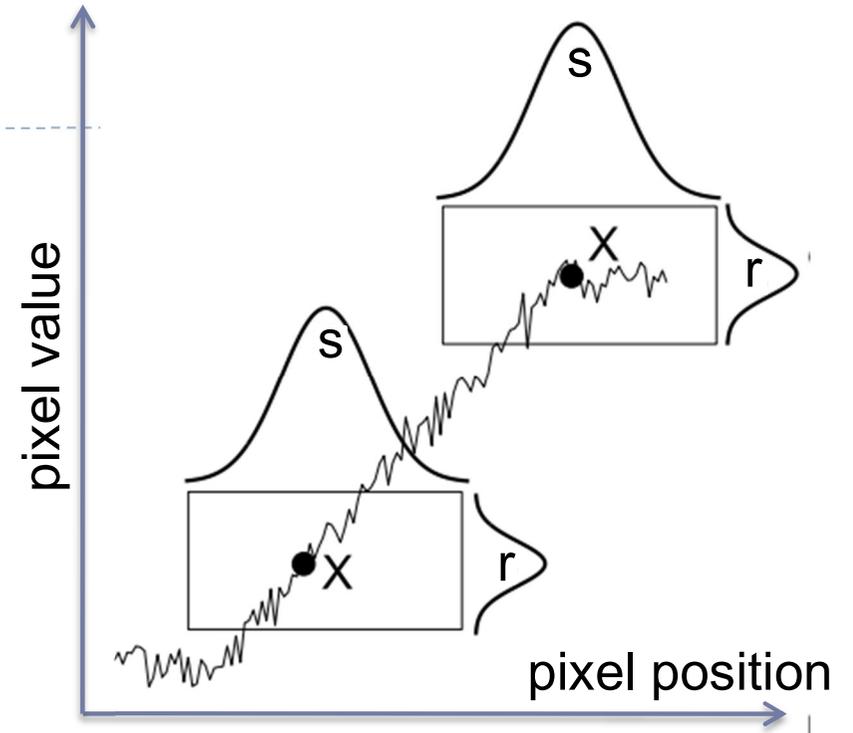

Pixel coordinates
 $\mathbf{p} = (i, j)$

Neighborhood of the pixel \mathbf{p}

$$w(\mathbf{p}, \mathbf{q}) = g_s(\mathbf{p} - \mathbf{q}) g_r(x(\mathbf{p}) - x(\mathbf{q}))$$

distance in the spatial position (x,y) distance (difference) in pixel values

$$g_s(\mathbf{d}) = \exp\left(\frac{-\|\mathbf{d}\|_2}{2\sigma_s^2}\right) \quad g_r(d) = \exp\left(\frac{-d^2}{2\sigma_r^2}\right)$$

How to make the bilateral filter fast?

- ▶ A number of approximations have been proposed
 - ▶ Combination of linear filters [Durand & Dorsey 2002, Yang et al. 2009]
 - ▶ Bilateral grid [Chen et al. 2007]
 - ▶ Permutohedral lattice [Adams et al. 2010]
 - ▶ Domain transform [Gastal & Oliveira 2011]

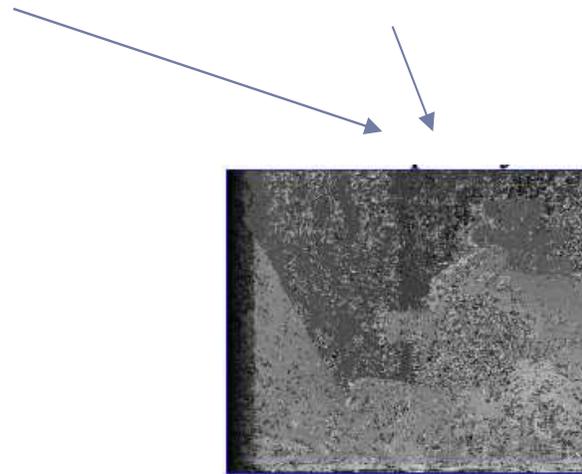

Joint-bilateral filter (a.k.a guided/cross b.f.)

- ▶ The “range” term does not need to operate in the same domain as the filter output

- ▶ Example:

Stereo image pair

Estimated left-to-right disparity

The “spatial”
term operates
on disparities

The “range”
term operates
on the colour
image

Joint bilateral
filter

Filtered disparity

A simplified
algorithm from
[Mueller et al. 2010]

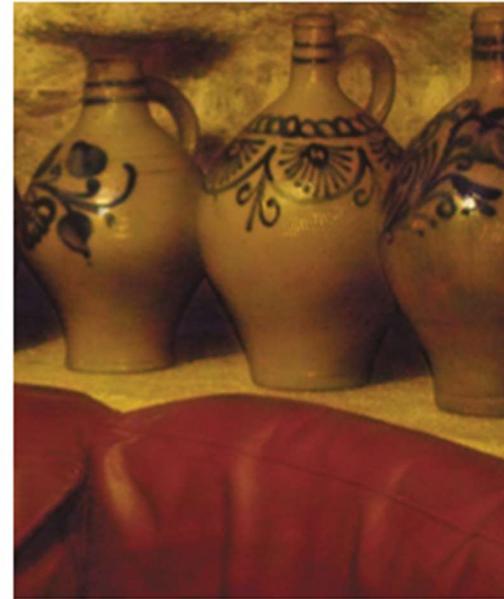

Joint bilateral filter: Flash / no-flash

Flash

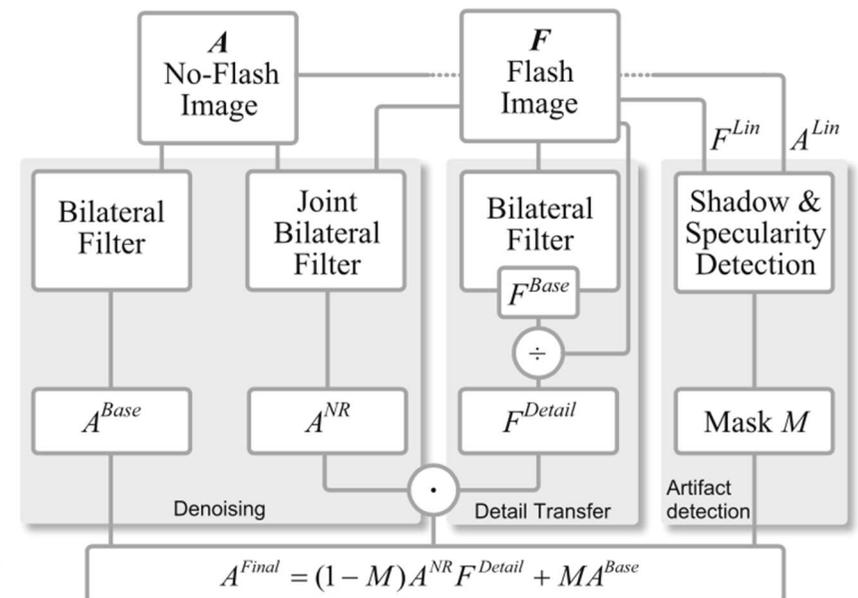

No-flash

Detail transfer with denoising

- ▶ Preserve colour and illumination from the no-flash image
- ▶ Use flash image to remove noise and add details
- ▶ [Petshnigg et al. 2004]

Example of edge preserving filtering

- ▶ Domain Transform for Edge-Aware Image and Video Processing
- ▶ Video:
 - ▶ <https://youtu.be/UllxhIIQrTY?t=4m10s>
 - ▶ From: <http://inf.ufrgs.br/~eslgastal/DomainTransform/>

UNIVERSITY OF

Advanced image processing

Part 1/2 – processing by optimization

Rafał Mantiuk

Computer Laboratory, University of Cambridge

Optimization-based methods

sources/destinations

cloning

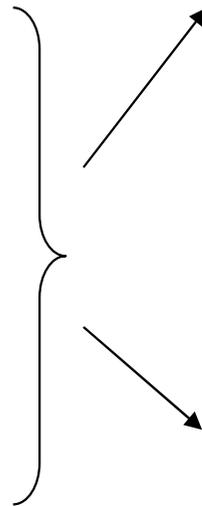

seamless cloning

Poisson image editing [Perez et al. 2003]

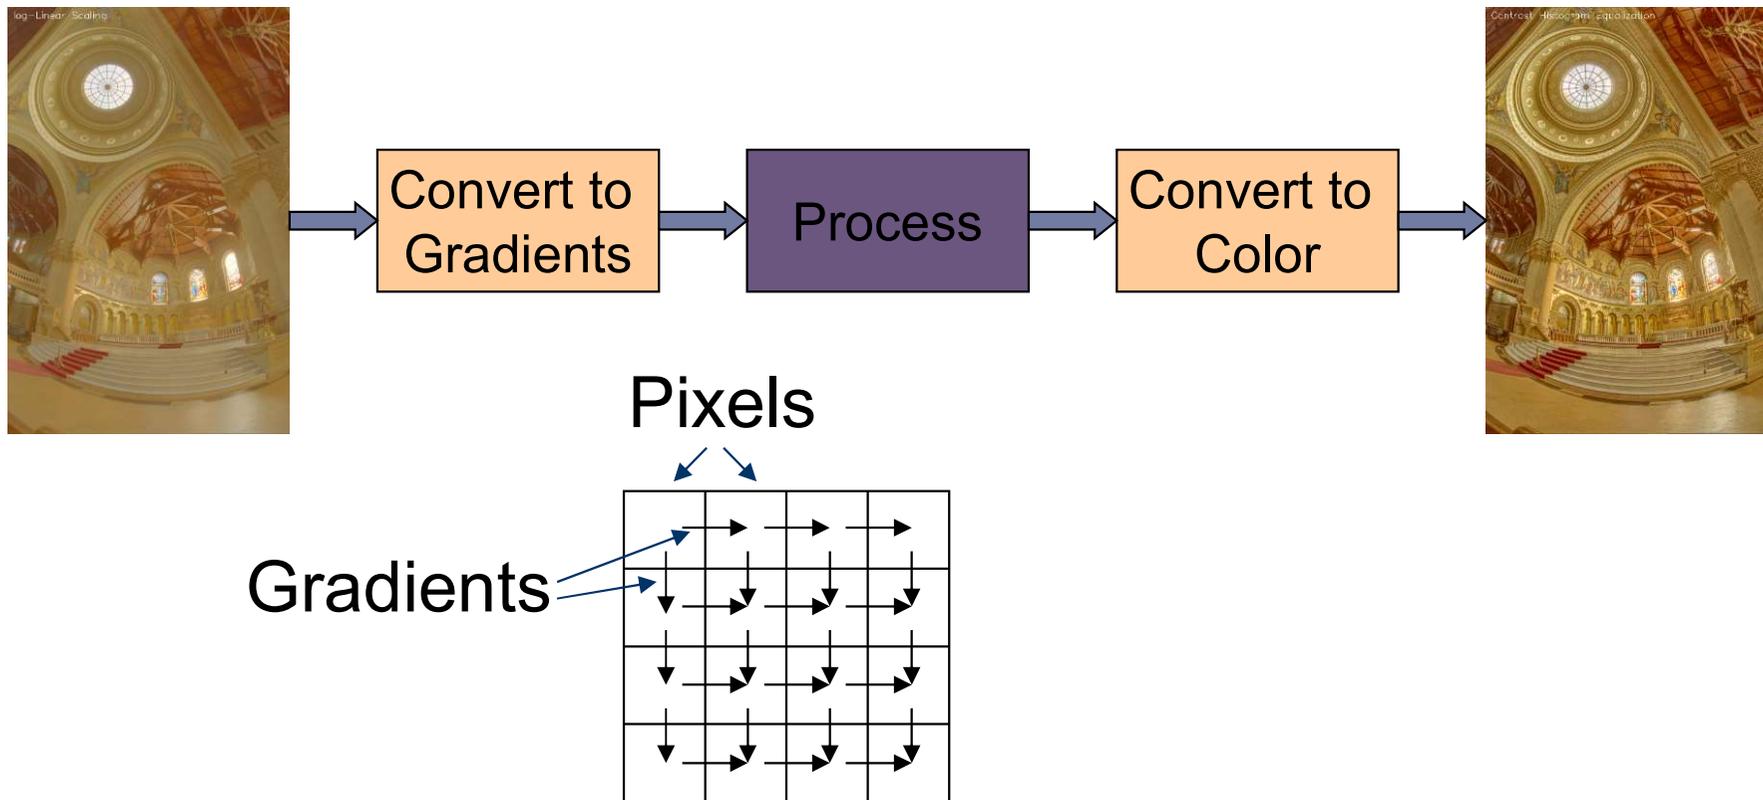

Gradient Domain compositing

► Compositing [Wang et al. 2004]

Gradient domain methods

- ▶ Operate on pixel gradients instead of pixel values

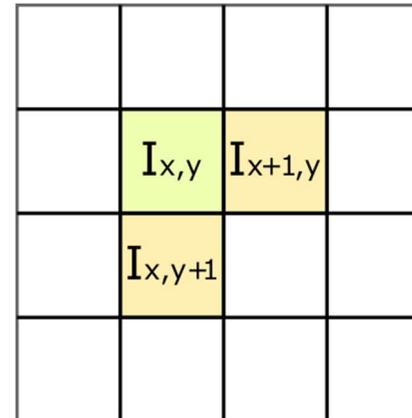

Forward Transformation

- ▶ Forward Transformation

- ▶ Compute gradients as differences between a pixel and its two neighbors

$$\nabla I_{x,y} = \begin{bmatrix} I_{x+1,y} - I_{x,y} \\ I_{x,y+1} - I_{x,y} \end{bmatrix}$$

- ▶ Result: 2D gradient map (2 x more values than the number of pixels)

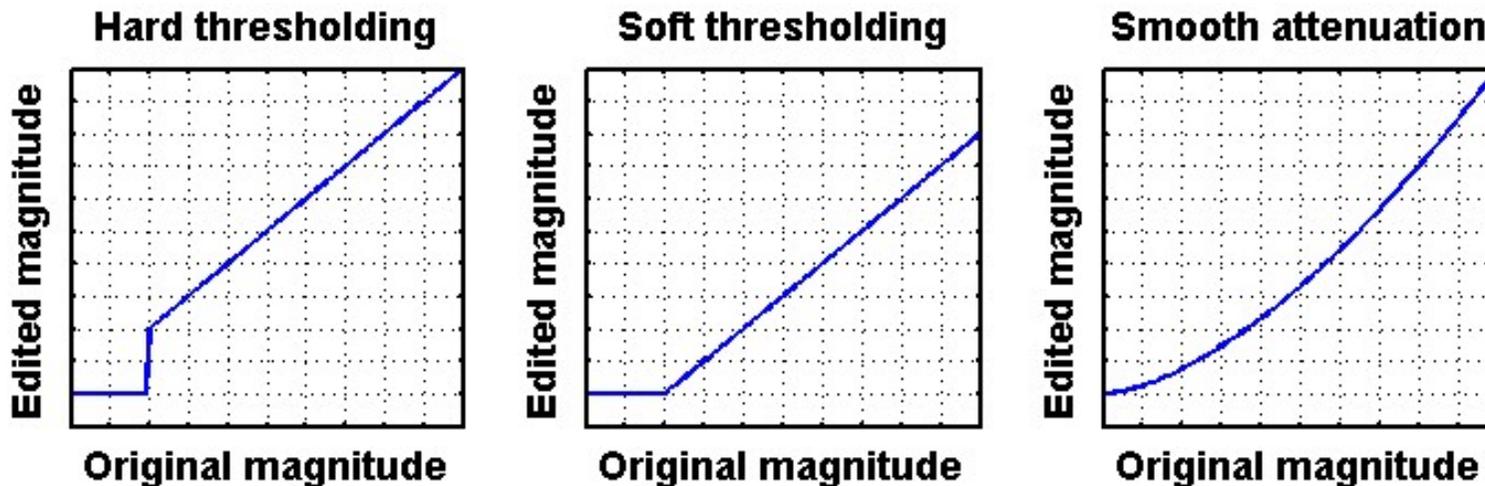

Processing gradient field

- Typically, gradient magnitudes are modified while gradient direction (angle) remains the same

$$G_{x,y} = \nabla I_{x,y} \cdot \frac{f(\|\nabla I_{x,y}\|)}{\|\nabla I_{x,y}\|}$$

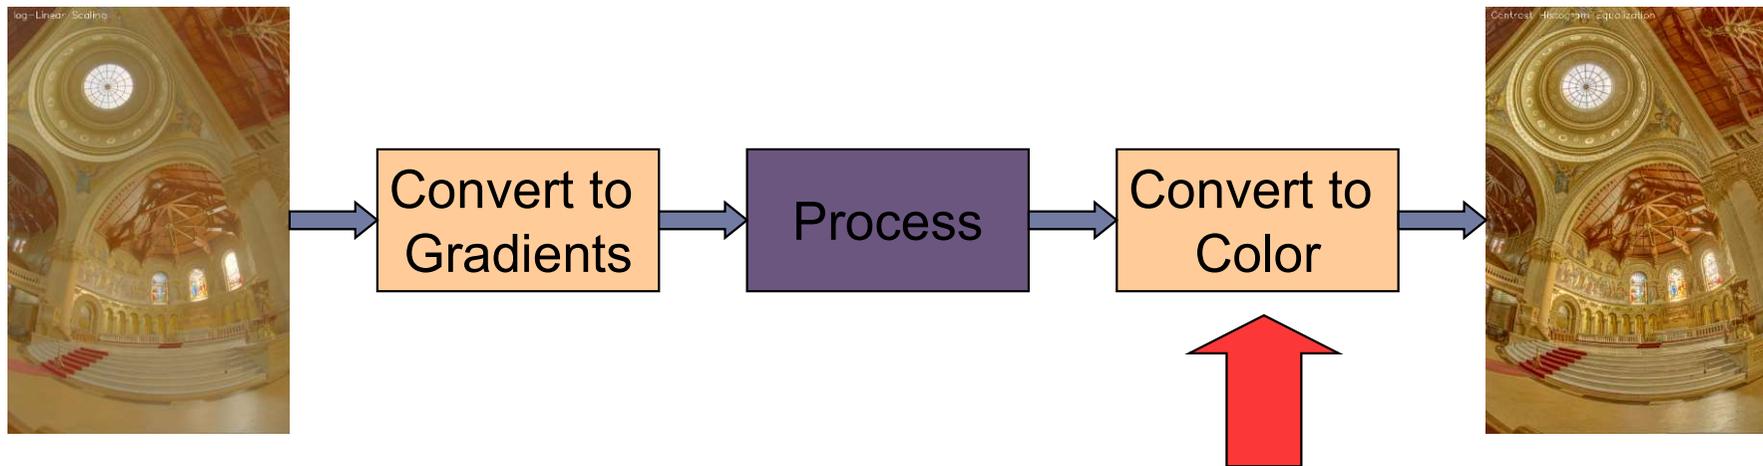

Gradient editing function

- Examples of gradient editing functions:

Inverse transform: the difficult part

- ▶ There is no straightforward transformation from gradients to luminance

- Instead, a minimization problem is solved:

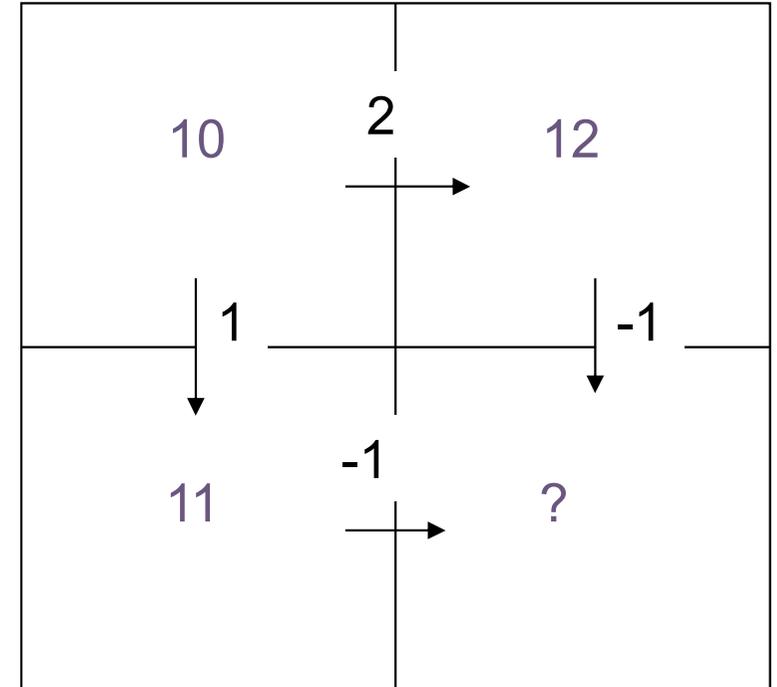

$$\arg \min_I \sum_{x,y} \left[\left(I_{x+1,y} - I_{x,y} - G_{x,y}^{(x)} \right)^2 + \left(I_{x,y+1} - I_{x,y} - G_{x,y}^{(y)} \right)^2 \right]$$

Image Pixels

Desired gradients

Inverse transformation

- ▶ Convert modified gradients to pixel values
 - ▶ Not trivial!
 - ▶ Most gradient fields are inconsistent - do not produce valid images
 - ▶ If no accurate solution is available, take the best possible solution
 - ▶ Analogy: system of springs

Gradient field reconstruction: derivation

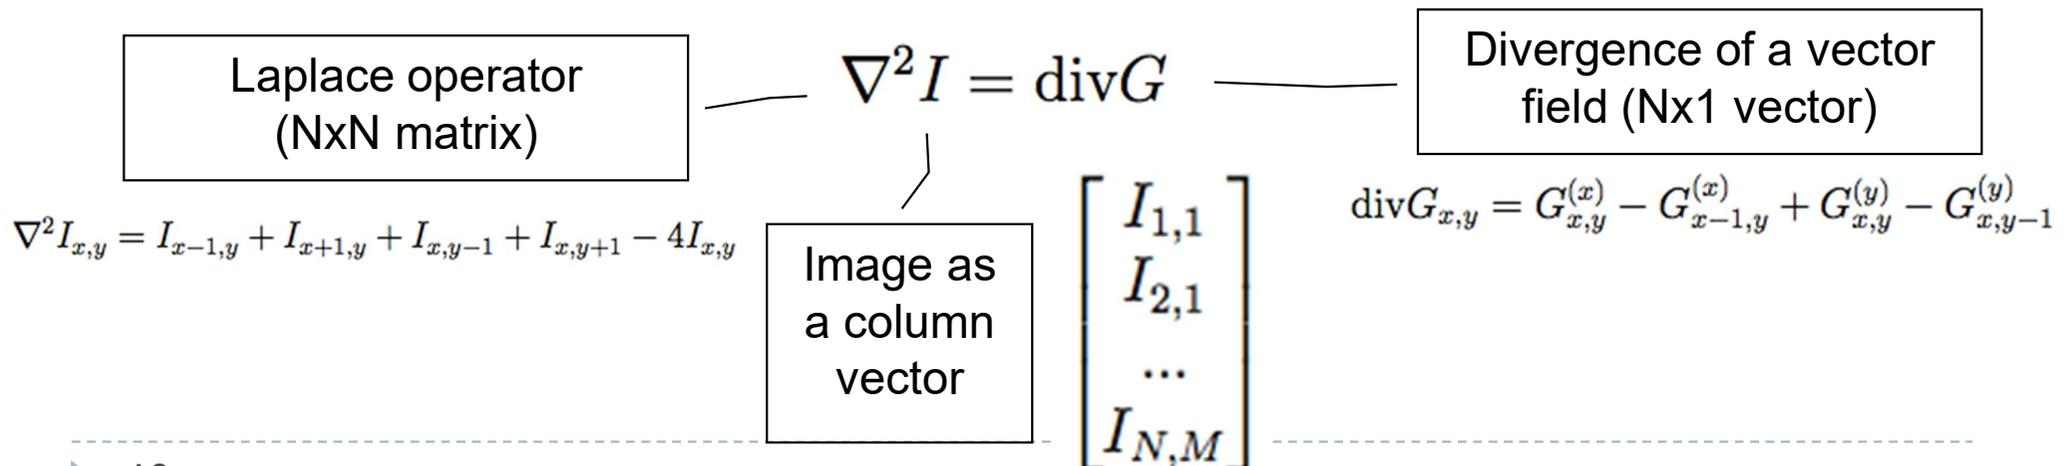

- ▶ The minimization problem is given by:

$$\arg \min_I \sum_{x,y} \left[\left(I_{x+1,y} - I_{x,y} - G_{x,y}^{(x)} \right)^2 + \left(I_{x,y+1} - I_{x,y} - G_{x,y}^{(y)} \right)^2 \right]$$

- ▶ After equating derivatives over pixel values to 0 we get:
 - ▶ Derivation done in the lecture

$$I_{x-1,y} + I_{x+1,y} + I_{x,y-1} + I_{x,y+1} - 4I_{x,y} = G_{x,y}^{(x)} - G_{x-1,y}^{(x)} + G_{x,y}^{(y)} - G_{x,y-1}^{(y)}$$

- ▶ In matrix notation:

Laplace operator for 3x3 image

$$\nabla^2 = \begin{bmatrix} -2 & 1 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 1 & -3 & 1 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & -2 & 0 & 0 & 1 & 0 & 0 & 0 \\ 1 & 0 & 0 & -3 & 1 & 0 & 1 & 0 & 0 \\ 0 & 1 & 0 & 1 & -4 & 1 & 0 & 1 & 0 \\ 0 & 0 & 1 & 0 & 1 & -3 & 0 & 0 & 1 \\ 0 & 0 & 0 & 1 & 0 & 0 & -2 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 1 & -3 & 1 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 1 & -2 \end{bmatrix}$$

Solving sparse linear systems

- ▶ Just use “\” operator in Matlab / Octave:
 - ▶ $x = A \setminus b$;
- ▶ Great “cookbook”:
 - ▶ TEUKOLSKY, S.A., FLANNERY, B.P., PRESS, W.H., AND VETTERLING, W.T. 1992. *Numerical recipes in C*. Cambridge University Press, Cambridge.
- ▶ Some general methods
 - ▶ Cosine-transform – fast but cannot work with weights (next slides) and may suffer from floating point precision errors
 - ▶ Multi-grid – fast, difficult to implement, not very flexible
 - ▶ Conjugate gradient / bi-conjugate gradient – general, memory efficient, iterative but fast converging
 - ▶ Cholesky decomposition – effective when working on sparse matrices

Pinching artefacts

- ▶ A common problem of gradient-based methods is that they may result in “pinching” artefacts (left image)
- ▶ Such artefacts can be avoided by introducing weights to the optimization problem

Weighted gradients

- ▶ The new objective function is:

$$\arg \min_I \sum_{x,y} \left[w_{x,y}^{(x)} (I_{x+1,y} - I_{x,y} - G_{x,y}^{(x)})^2 + w_{x,y}^{(y)} (I_{x,y+1} - I_{x,y} - G_{x,y}^{(y)})^2 \right]$$

- ▶ so that higher weights are assigned to low gradient magnitudes (in the original image).

$$w_{x,y}^{(x)} = w_{x,y}^{(y)} = \frac{1}{\|\nabla I_{x,y}^{(o)}\| + \epsilon}$$

- ▶ The linear system can be derived again
 - ▶ but this is a lot of work and is error-prone

Weighted gradients - matrix notation (1)

- ▶ The objective function:

$$\arg \min_I \sum_{x,y} \left[w_{x,y}^{(x)} (I_{x+1,y} - I_{x,y} - G_{x,y}^{(x)})^2 + w_{x,y}^{(y)} (I_{x,y+1} - I_{x,y} - G_{x,y}^{(y)})^2 \right]$$

- ▶ In the matrix notation (without weights for now):

$$\arg \min_I \left\| \begin{bmatrix} \nabla_x \\ \nabla_y \end{bmatrix} I - \begin{bmatrix} G^{(x)} \\ G^{(y)} \end{bmatrix} \right\|^2$$

- ▶ Gradient operators (for 3x3 pixel image):

$$\nabla_x = \begin{bmatrix} -1 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & -1 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & -1 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & -1 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix}$$

$$\nabla_y = \begin{bmatrix} -1 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & -1 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & -1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & -1 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & -1 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix}$$

Weighted gradients - matrix notation (2)

- ▶ The objective function again:

$$\arg \min_I \left\| \begin{bmatrix} \nabla_x \\ \nabla_y \end{bmatrix} I - \begin{bmatrix} G^{(x)} \\ G^{(y)} \end{bmatrix} \right\|^2$$

- ▶ Such over-determined least-square problem can be solved using pseudo-inverse:

$$\begin{bmatrix} \nabla'_x & \nabla'_y \end{bmatrix} \begin{bmatrix} \nabla_x \\ \nabla_y \end{bmatrix} I = \begin{bmatrix} \nabla'_x & \nabla'_y \end{bmatrix} \begin{bmatrix} G^{(x)} \\ G^{(y)} \end{bmatrix}$$

- ▶ Or simply:

$$\left(\nabla'_x \nabla_x + \nabla'_y \nabla_y \right) I = \nabla'_x G^{(x)} + \nabla'_y G^{(y)}$$

- ▶ With weights:

$$\left(\nabla'_x W \nabla_x + \nabla'_y W \nabla_y \right) I = \nabla'_x W G^{(x)} + \nabla'_y W G^{(y)}$$

WLS filter: Edge stopping filter by optimization

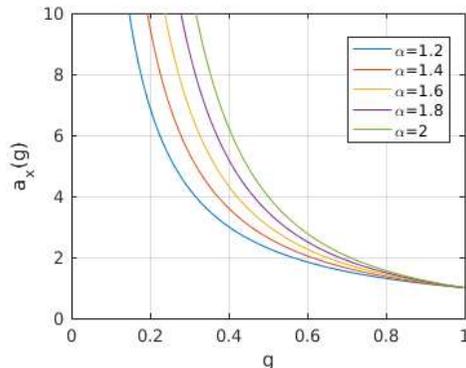

► Weighted-least-squares optimization

Make reconstructed image u possibly close to input g

Smooth out the image by making partial derivatives close to 0

$$\operatorname{argmin}_{\mathbf{u}} \sum_p \left((u_p - g_p)^2 + \lambda \left(a_{x,p}(g) \left(\frac{\partial u}{\partial x} \right)_p^2 + a_{y,p}(g) \left(\frac{\partial u}{\partial y} \right)_p^2 \right) \right)$$

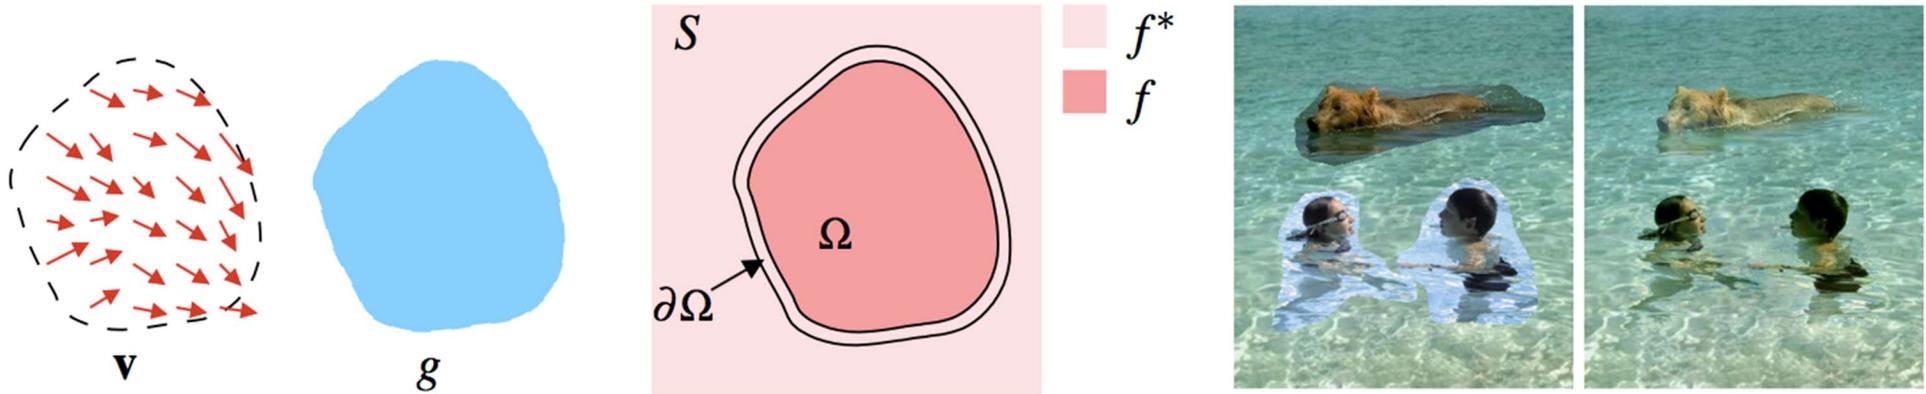

Spatially varying smoothing – less smoothing near the edges

$$a_{x,p}(g) = \frac{1}{\left| \frac{\partial u}{\partial x} (g) \right|^\alpha + \epsilon}$$

Advanced Graphics & Image Processing

Parallel programming in OpenCL

Part 1/3 – OpenCL framework

Rafał Mantiuk

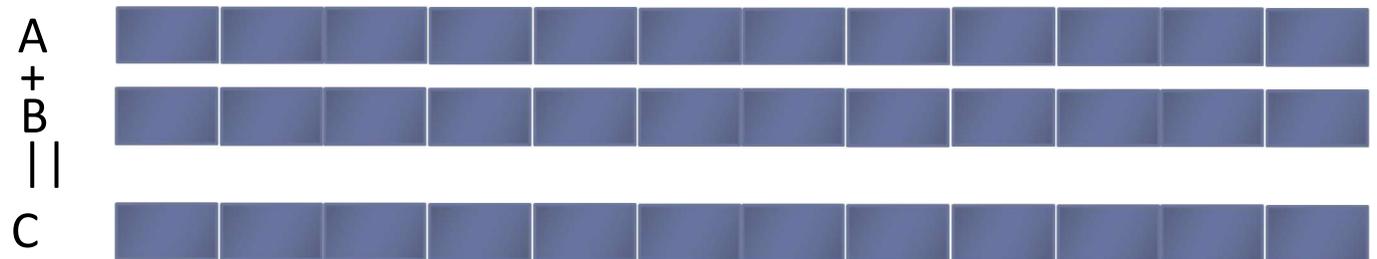

Computer Laboratory, University of Cambridge

Single Program Multiple Data (SPMD)

- ▶ Consider the following vector addition example

Serial program:
one program completes
the entire task

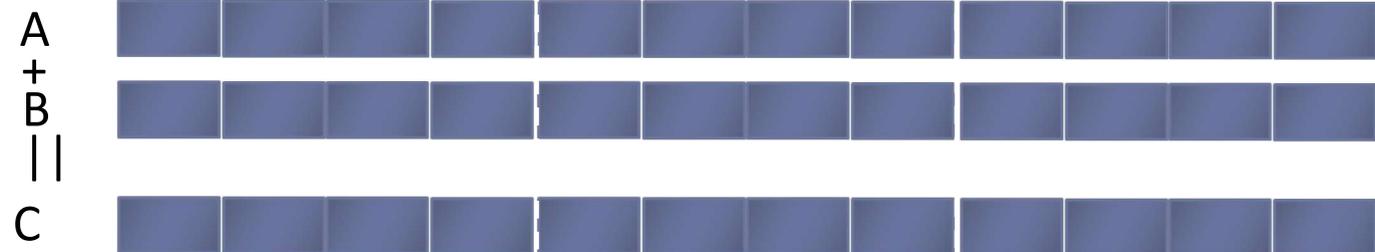

```
for( i = 0:11 ) {  
    C[ i ] = A[ i ] + B[ i ]  
}
```

Multiple copies of the same program execute on different data in parallel

SPMD program:
multiple copies of the
same program run on
different chunks of the
data

```
for( i = 0:3 ) {  
    C[ i ] = A[ i ] + B[ i ]  
}  
for( i = 4:7 ) {  
    C[ i ] = A[ i ] + B[ i ]  
}  
for( i = 8:11 ) {  
    C[ i ] = A[ i ] + B[ i ]  
}
```

Parallel Software – SPMD

- ▶ In the vector addition example, each chunk of data could be executed as an independent thread
- ▶ On modern CPUs, the overhead of creating threads is so high that the chunks need to be large
 - ▶ In practice, usually a few threads (about as many as the number of CPU cores) and each is given a large amount of work to do
- ▶ For GPU programming, there is low overhead for thread creation, so we can create one thread per loop iteration

Parallel Software – SPMD

 = loop iteration

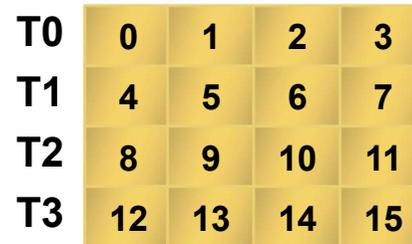

Single-threaded (CPU)

```
// there are N elements
for(i = 0; i < N; i++)
    C[i] = A[i] + B[i]
```

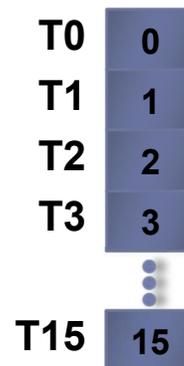

Multi-threaded (CPU)

```
// tid is the thread id
// P is the number of cores
for(i = 0; i < tid*N/P; i++)
    C[i] = A[i] + B[i]
```

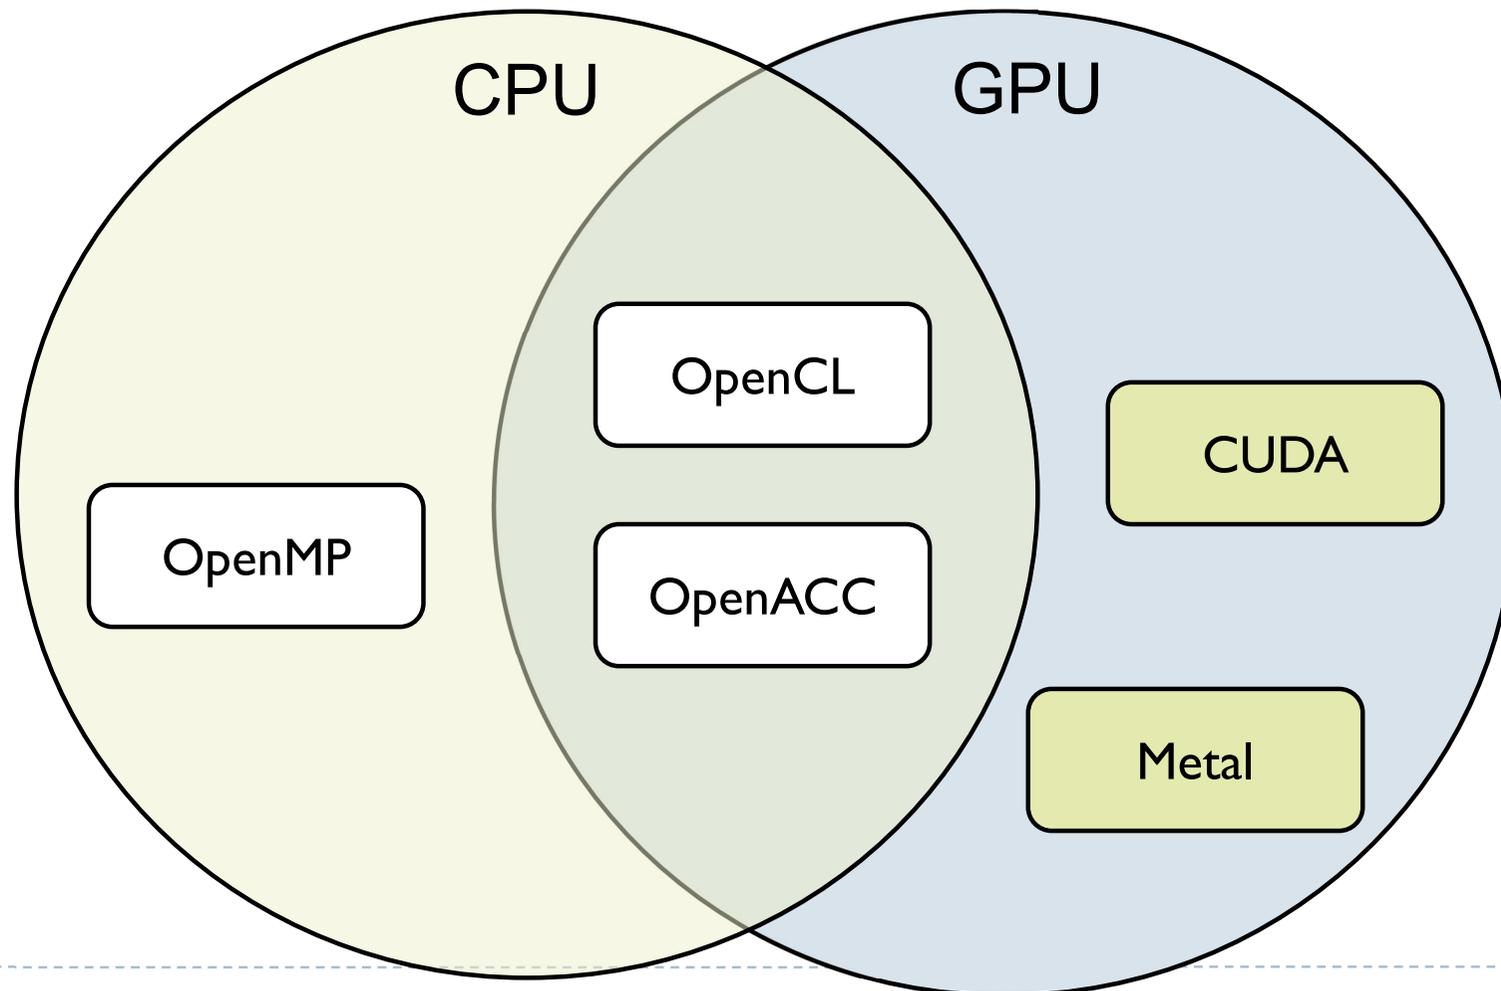

Massively Multi-threaded (GPU)

```
// tid is the thread id
C[tid] = A[tid] + B[tid]
```

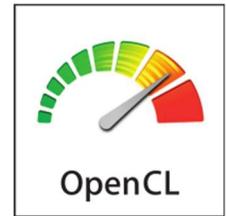

Parallel programming frameworks

- ▶ These are some of more relevant frameworks for creating parallelized code

OpenCL

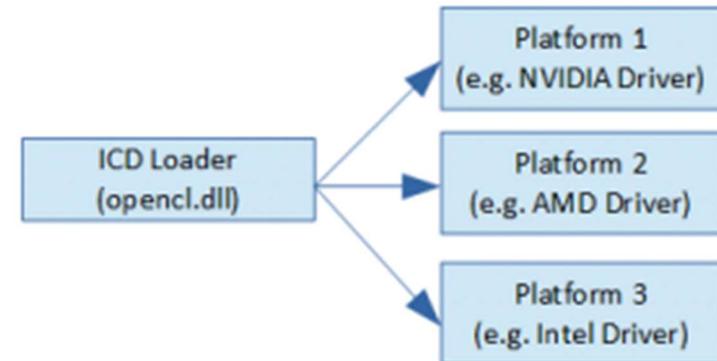

- ▶ OpenCL is a framework for writing parallelized code for CPUs, GPUs, DSPs, FPGAs and other processors
- ▶ Initially developed by Apple, now supported by AMD, IBM, Qualcomm, Intel and Nvidia
- ▶ Versions
 - ▶ Latest: OpenCL 3.0
 - ▶ OpenCL C++ kernel language
 - ▶ SPIR-V as intermediate representation for kernels
 - Vulkan uses the same Standard Portable Intermediate Representation
 - ▶ AMD, Intel, Nvidia
 - ▶ Mostly supported: OpenCL 1.2
 - ▶ OSX, older GPUs

OpenCL platforms and drivers

- ▶ To run OpenCL code you need:

- ▶ Generic ICD loader
 - ▶ Included in the OS
- ▶ Installable Client Driver
 - ▶ From Nvidia, Intel, etc.

- ▶ This applies to Windows and Linux, only one platform on Mac

- ▶ To develop OpenCL code you need:

- ▶ OpenCL headers/libraries
 - ▶ Included in the SDKs
 - Nvidia – CUDA Toolkit
 - Intel OpenCL SDK
 - ▶ But lightweight options are also available

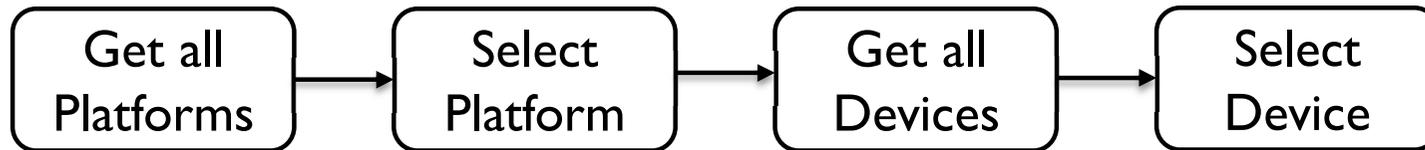

Programming OpenCL

- ▶ OpenCL natively offers C99 API
- ▶ But there is also a standard OpenCL C++ API wrapper
 - ▶ Strongly recommended – reduces the amount of code
- ▶ Programming OpenCL is similar to programming shaders in OpenGL
 - ▶ Host code runs on CPU and invokes **kernels**
 - ▶ Kernels are written in C-like programming language
 - ▶ In many respects similar to GLSL
 - ▶ Kernels are passed to API as strings and compiled at runtime
 - ▶ Kernels are usually stored in text files
 - ▶ Kernels can be precompiled into SPIR from OpenCL 2.1

Example: Step 1 - Select device

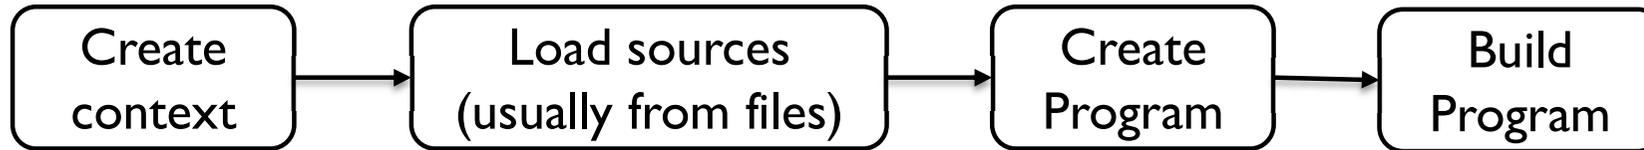

```
//get all platforms (drivers)
std::vector<cl::Platform> all_platforms;
cl::Platform::get(&all_platforms);
if (all_platforms.size() == 0){
    std::cout << " No platforms found. Check OpenCL installation!\n";
    exit(1);
}
cl::Platform default_platform = all_platforms[0];
std::cout << "Using platform: " << default_platform.getInfo<CL_PLATFORM_NAME>() << "\n";

//get default device of the default platform
std::vector<cl::Device> all_devices;
default_platform.getDevices(CL_DEVICE_TYPE_ALL, &all_devices);
if (all_devices.size() == 0){
    std::cout << " No devices found. Check OpenCL installation!\n";
    exit(1);
}
cl::Device default_device = all_devices[0];
std::cout << "Using device: " << default_device.getInfo<CL_DEVICE_NAME>() << "\n";
```

Example: Step 2 - Build program

```
cl::Context context({ default_device });
```

```
cl::Program::Sources sources;
```

```
// kernel calculates for each element C=A+B
```

```
std::string kernel_code =
```

```
    "__kernel void simple_add(__global const int* A, __global const int* B, __global int* C) {"  
    "    int index = get_global_id(0);"  
    "    C[index] = A[index] + B[index];"  
    "};";
```

```
sources.push_back({ kernel_code.c_str(), kernel_code.length() });
```

```
cl::Program program(context, sources);
```

```
try {
```

```
    program.build({ default_device });
```

```
}
```

```
catch (cl::Error err) {
```

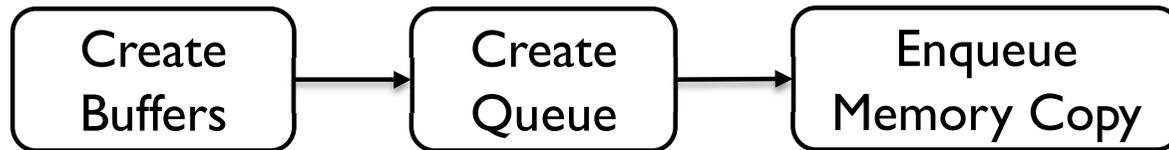

```
    std::cout << " Error building: " <<
```

```
        program.getBuildInfo<CL_PROGRAM_BUILD_LOG>(default_device) << "\n";
```

```
    exit(1);
```

```
}
```

Example: Step 3 - Create Buffers and copy memory

```
// create buffers on the device
cl::Buffer buffer_A(context, CL_MEM_READ_WRITE, sizeof(int) * 10);
cl::Buffer buffer_B(context, CL_MEM_READ_WRITE, sizeof(int) * 10);
cl::Buffer buffer_C(context, CL_MEM_READ_WRITE, sizeof(int) * 10);

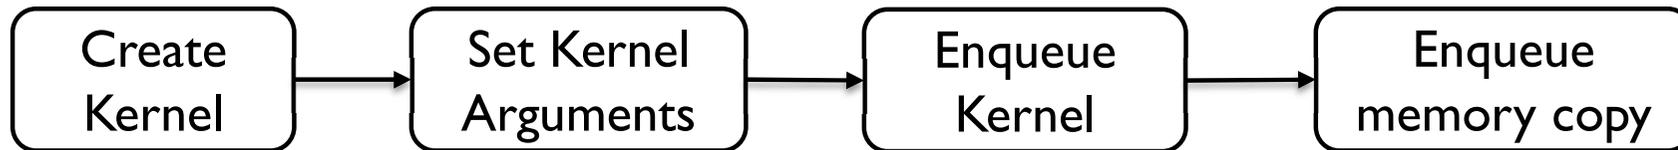

int A[] = { 0, 1, 2, 3, 4, 5, 6, 7, 8, 9 };
int B[] = { 0, 1, 2, 0, 1, 2, 0, 1, 2, 0 };

//create queue to which we will push commands for the device.
cl::CommandQueue queue(context, default_device);

//write arrays A and B to the device
queue.enqueueWriteBuffer(buffer_A, CL_TRUE, 0, sizeof(int) * 10, A);
queue.enqueueWriteBuffer(buffer_B, CL_TRUE, 0, sizeof(int) * 10, B);
```

Example: Step 4 - Execute Kernel and retrieve the results

```
cl::Kernel kernel(program, "simple_add");

kernel.setArg(0, buffer_A);
kernel.setArg(1, buffer_B);
kernel.setArg(2, buffer_C);
queue.enqueueNDRangeKernel(kernel, cl::NullRange, cl::NDRange(10), cl::NullRange);

int C[10];
//read result C from the device to array C
queue.enqueueReadBuffer(buffer_C, CL_TRUE, 0, sizeof(int) * 10, C);
queue.finish();

std::cout << " result: \n";
for (int i = 0; i < 10; i++){
    std::cout << C[i] << " ";
}
std::cout << std::endl;
```

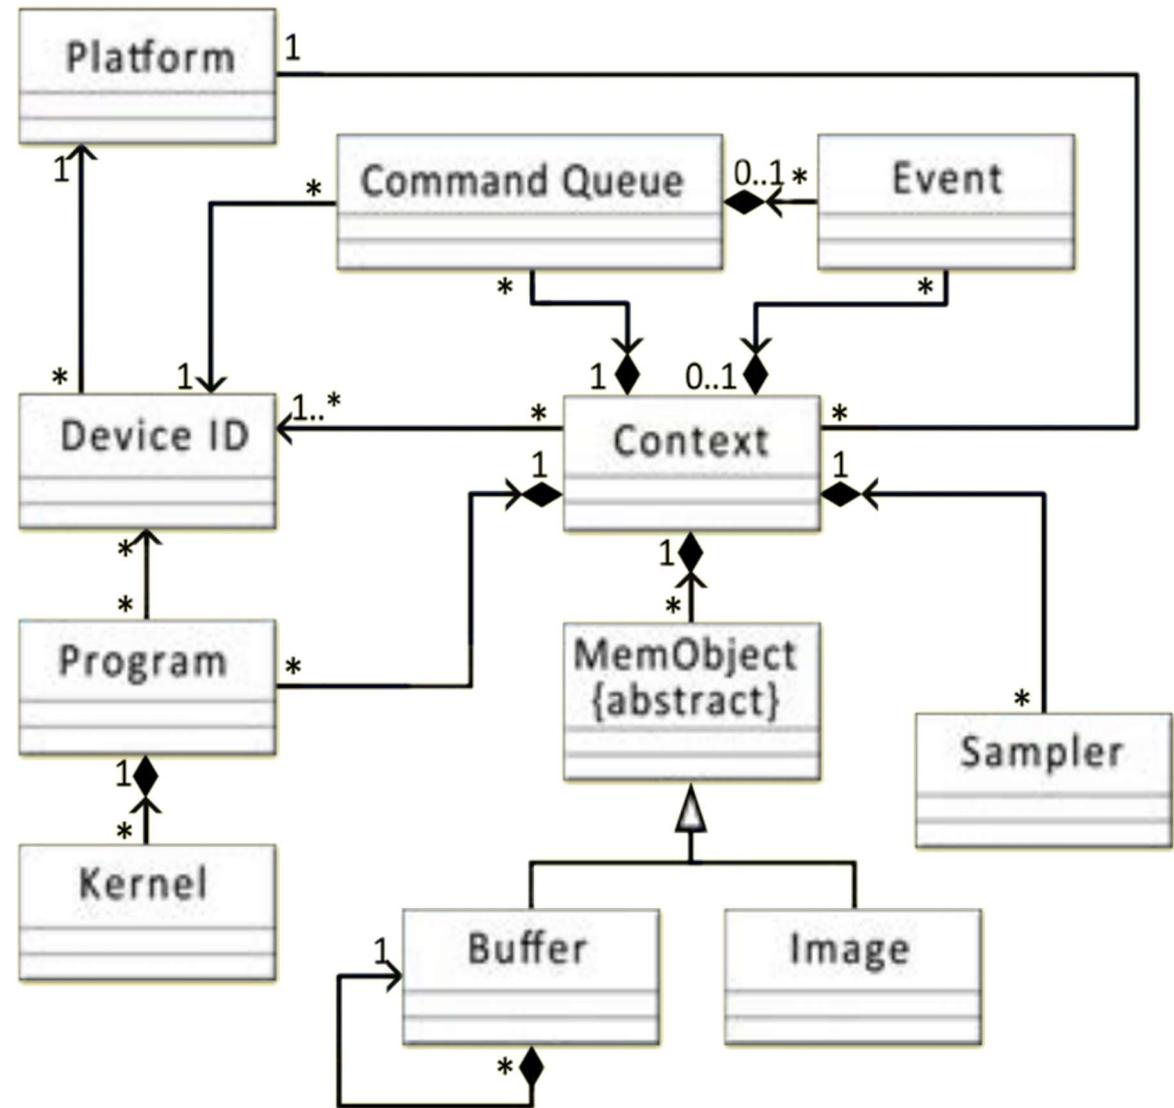

Our Kernel was

```
__kernel void simple_add(__read_only const int* A,
                        __read_only const int* B,
                        __write_only int* C) {

    int index = get_global_id(0);
    C[index]=A[index]+B[index];
};
```

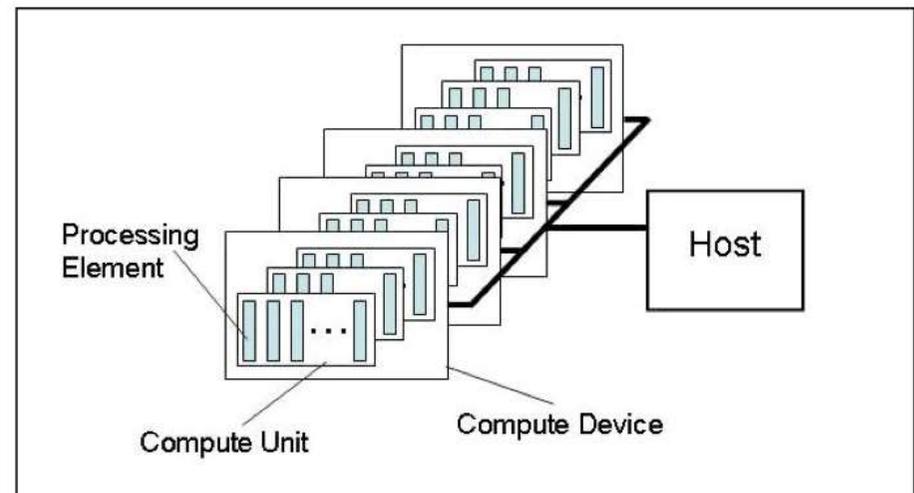

OpenCL API Class Diagram

- ▶ *Platform* – Nvidia CUDA
- ▶ *Device* – GeForce 1080
- ▶ *Program* – collection of kernels
- ▶ *Buffer or Image* – device memory
- ▶ *Sampler* – how to interpolate values for *Image*
- ▶ *Command Queue* – put a sequence of operations there
- ▶ *Event* – to notify that something has been done

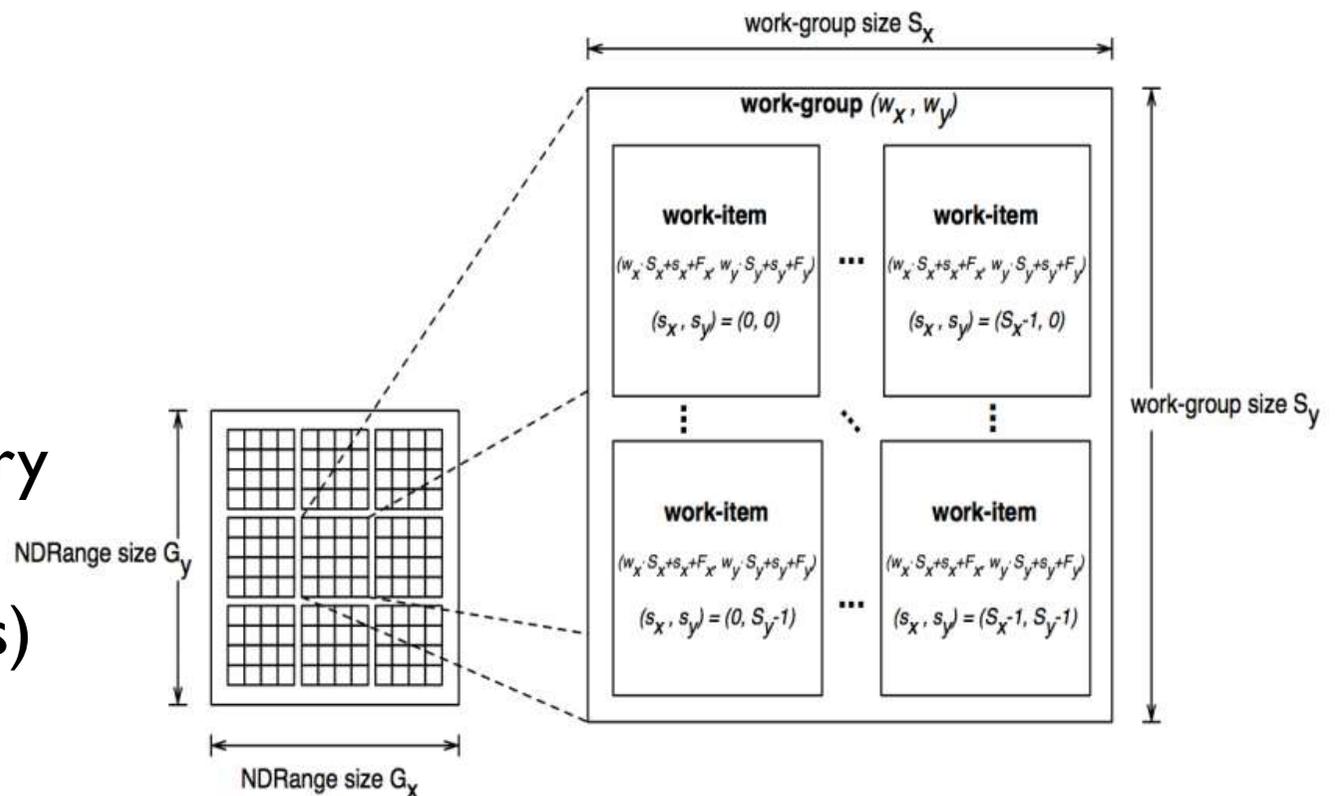

Platform model

- ▶ The host is whatever the OpenCL library runs on
 - ▶ Usually x86 CPUs for both NVIDIA and AMD
- ▶ Devices are processors that the library can talk to
 - ▶ CPUs, GPUs, DSPs and generic accelerators
- ▶ For AMD
 - ▶ All CPUs are combined into a single device (each core is a compute unit and processing element)
 - ▶ Each GPU is a separate device

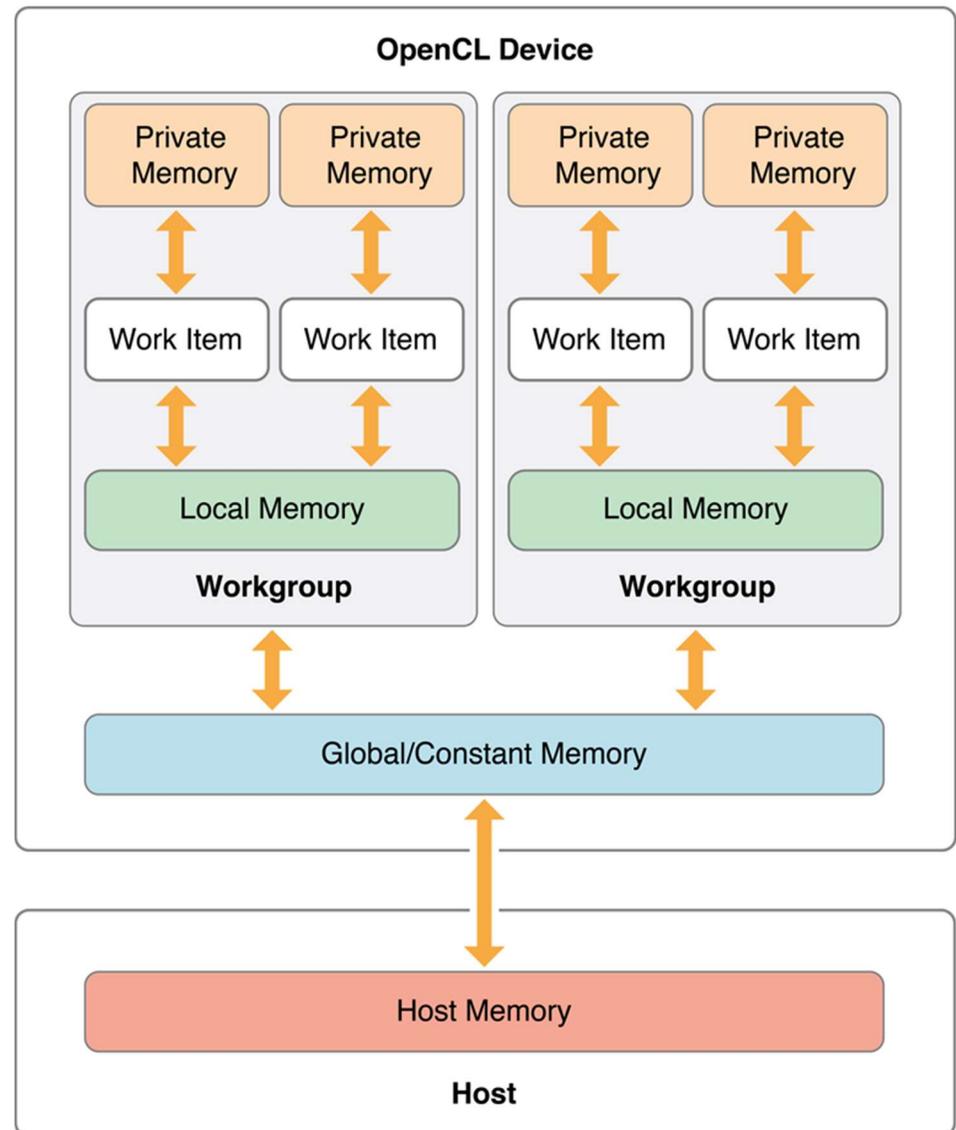

Execution model

- ▶ Each kernel executes on 1D, 2D or 3D array (NDRange)
- ▶ The array is split into work-groups
- ▶ Work items (threads) in each work-group share some local memory
- ▶ Kernel can query
 - ▶ `get_global_id(dim)`
 - ▶ `get_group_id(dim)`
 - ▶ `get_local_id(dim)`
- ▶ Work items are not bound to any memory entity (unlike GLSL shaders)

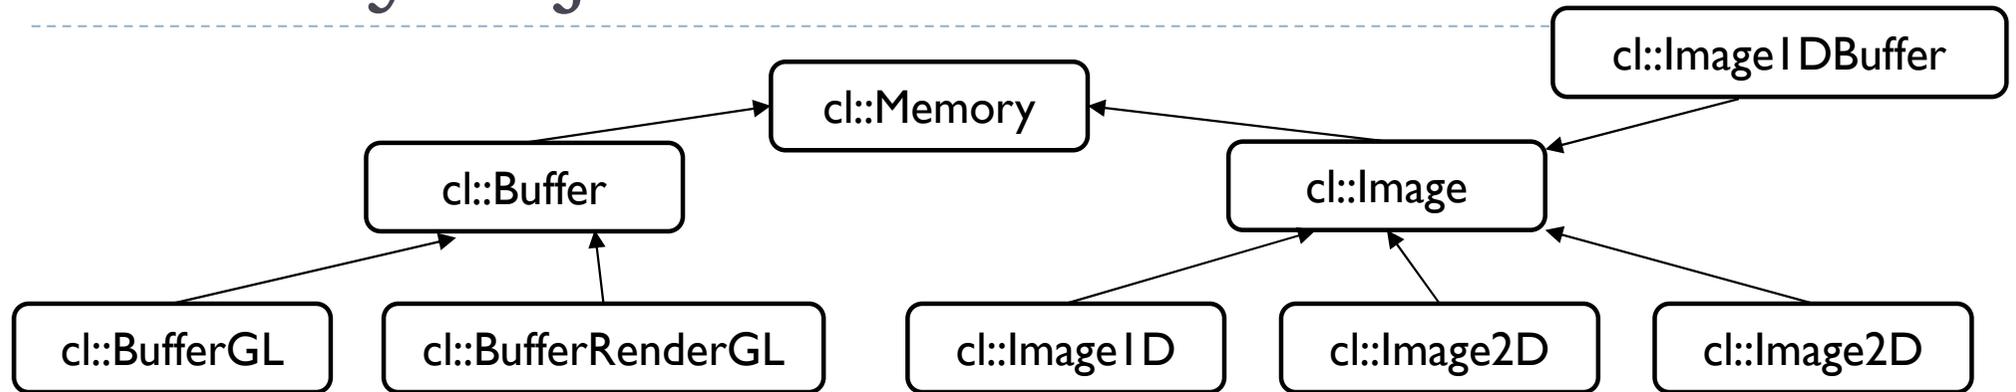

Memory model

- ▶ **Host memory**
 - ▶ Usually CPU memory, device does not have access to that memory
- ▶ **Global memory [`__global`]**
 - ▶ Device memory, for storing large data
- ▶ **Constant memory [`__constant`]**
- ▶ **Local memory [`__local`]**
 - ▶ Fast, accessible to all work-items (threads) within a workgroup
- ▶ **Private memory [`__private`]**
 - ▶ Accessible to a single work-item (thread)

Memory objects

This diagram is incomplete – there are more memory objects

▶ Buffer

- ▶ ArrayBuffer in OpenGL
- ▶ Accessed directly via C pointers

▶ Image

- ▶ Texture in OpenGL
- ▶ Access via texture look-up function
- ▶ Can interpolate values, clamp, etc.

Programming model

- ▶ Data parallel programming
 - ▶ Each NDRange element is assigned to a work-item (thread)
 - ▶ Each kernel can use vector-types of the device (float4, etc.)
- ▶ Task-parallel programming
 - ▶ Multiple different kernels can be executed in parallel
- ▶ Command queue

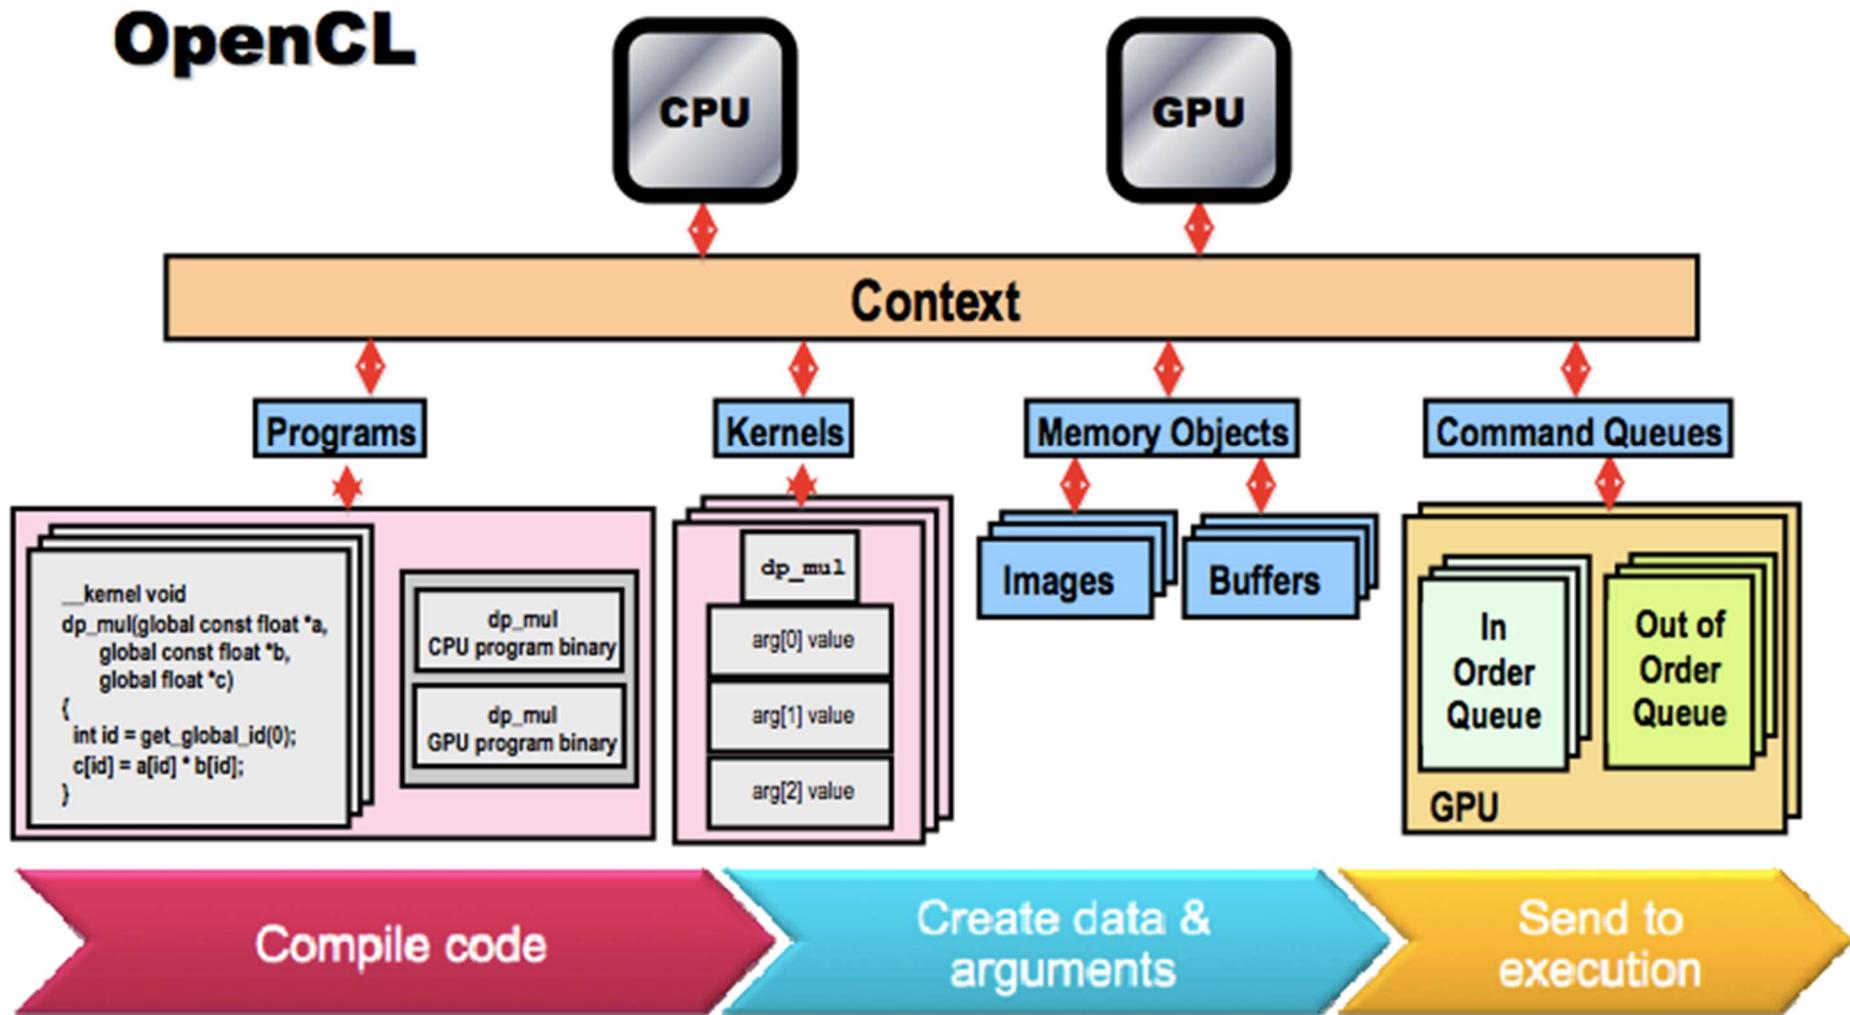

```
clCreateCommandQueue(  
    cl_context context,  
    cl_device_id device,  
    cl_command_queue_properties properties,  
    cl_int* errcode_ret)
```

CL_QUEUE_OUT_OF_ORDER_EXEC_MODE_ENABLE
Execute out-of-order if specified, in order otherwise

- ▶ Provides means to both synchronize kernels and execute them in parallel
-

Big Picture

Parallel programming in OpenCL

Part 2/3 – Thread mapping

Rafał Mantiuk

Computer Laboratory, University of Cambridge

Thread Mapping

- ▶ By using different mappings, the same thread can be assigned to access different data elements
 - ▶ The examples below show three different possible mappings of threads to data (assuming the thread id is used to access an element)

Mapping

```
int tid =
get_global_id(1) *
get_global_size(0) +
get_global_id(0);
```

```
int tid =
get_global_id(0) *
get_global_size(1) +
get_global_id(1);
```

```
int group_size =
get_local_size(0) *
get_local_size(1);
```

```
int tid =
get_group_id(1) *
get_num_groups(0) *
group_size +
get_group_id(0) *
group_size +
get_local_id(1) *
get_local_size(0) +
get_local_id(0)
```

Thread IDs

0	1	2	3
4	5	6	7
8	9	10	11
12	13	14	15

0	4	8	12
1	5	9	13
2	6	10	14
3	7	11	15

0	1	4	5
2	3	6	7
8	9	12	13
10	11	14	15

Thread Mapping

- ▶ Consider a serial matrix multiplication algorithm

```
for(i1=0; i1 < M; i1++)  
  for(i2=0; i2 < N; i2++)  
    for(i3=0; i3 < P; i3++)  
      C[i1][i2] += A[i1][i3]*B[i3][i2];
```

- ▶ This algorithm is suited for output data decomposition
 - ▶ We will create $N \times M$ threads
 - ▶ Effectively removing the outer two loops
 - ▶ Each thread will perform P calculations
 - ▶ The inner loop will remain as part of the kernel
- ▶ Should the index space be $M \times N$ or $N \times M$?

Thread Mapping

- ▶ Thread mapping 1: with an $M \times N$ index space, the kernel would be:

```
int tx = get_global_id(0);
int ty = get_global_id(1);
for(i3=0; i3<P; i3++)
    C[tx][ty] += A[tx][i3]*B[i3][ty];
```

Mapping for C

0	4	8	12
1	5	9	13
2	6	10	14
3	7	11	15

- ▶ Thread mapping 2: with an $N \times M$ index space, the kernel would be:

```
int tx = get_global_id(0);
int ty = get_global_id(1);
for(i3=0; i3<P; i3++)
    C[ty][tx] += A[ty][i3]*B[i3][tx];
```

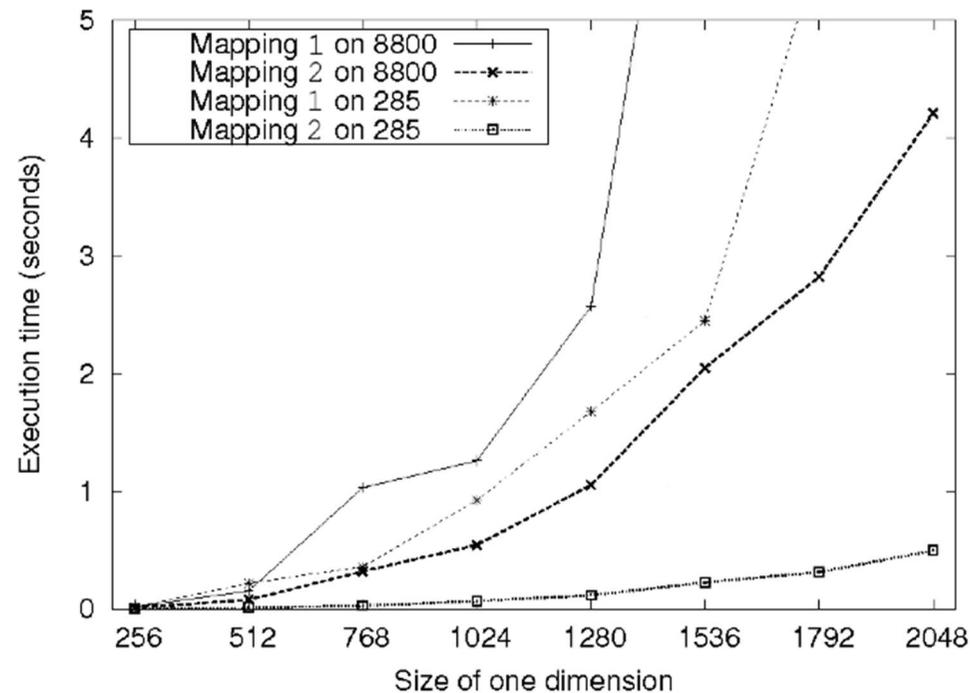

Mapping for C

0	1	2	3
4	5	6	7
8	9	10	11
12	13	14	15

- ▶ Both mappings produce functionally equivalent versions of the program

Thread Mapping

- ▶ This figure shows the execution of the two thread mappings on NVIDIA GeForce 285 and 8800 GPUs

- ▶ Notice that mapping 2 is far superior in performance for both GPUs

Thread Mapping

- ▶ The discrepancy in execution times between the mappings is due to data accesses on the global memory bus
 - ▶ Assuming row-major data, data in a row (i.e., elements in adjacent columns) are stored sequentially in memory
 - ▶ To ensure coalesced accesses, consecutive threads in the same wavefront should be mapped to columns (the second dimension) of the matrices
 - ▶ This will give coalesced accesses in Matrices B and C
 - ▶ For Matrix A, the iterator i_3 determines the access pattern for row-major data, so thread mapping does not affect it

UNIVERSITY OF
CAMBRIDGE
COMPUTER LABORATORY

Advanced Graphics & Image Processing

Parallel programming in OpenCL

Part 3/3 – Reduction

Rafał Mantiuk

Computer Laboratory, University of Cambridge

Reduction

- ▶ GPU offers very good performance for tasks in which the results are stored independently
 - ▶ Process N data items and store in N memory location

```
float reduce_sum(float* input, int length)
{
    float accumulator = input[0];
    for(int i = 1; i < length; i++)
        accumulator += input[i];
    return accumulator;
}
```

- ▶ But many common operations require reducing N values into 1 or few values
 - ▶ sum, min, max, prod, min, histogram, ...
- ▶ Those operations require an efficient implementation of reduction
- ▶ The following slides are based on AMD's OpenCL™ Optimization Case Study: Simple Reductions
 - ▶ <http://developer.amd.com/resources/articles-whitepapers/opencl-optimization-case-study-simple-reductions/>

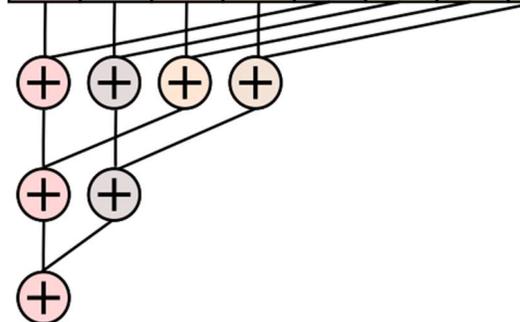

Reduction tree for the min operation

```
__kernel
void reduce_min(__global float* buffer,
               __local float* scratch,
               __const int length,
               __global float* result) {

    int global_index = get_global_id(0);
    int local_index = get_local_id(0);
    // Load data into local memory
    if (global_index < length) {
        scratch[local_index] = buffer[global_index];
    } else {
        scratch[local_index] = INFINITY;
    }
    barrier(CLK_LOCAL_MEM_FENCE);
    for(int offset = get_local_size(0) / 2;
        offset > 0; offset >>= 1) {
        if (local_index < offset) {
            float other = scratch[local_index + offset];
            float mine = scratch[local_index];
            scratch[local_index] = (mine < other) ? mine :
other;
        }
        barrier(CLK_LOCAL_MEM_FENCE);
    }
    if (local_index == 0) {
        result[get_group_id(0)] = scratch[0];
    }
}
```

- ▶ barrier ensures that all threads (work units) in the local group reach that point before execution continue
- ▶ Each iteration of the for loop computes next level of the reduction pyramid

Local memory

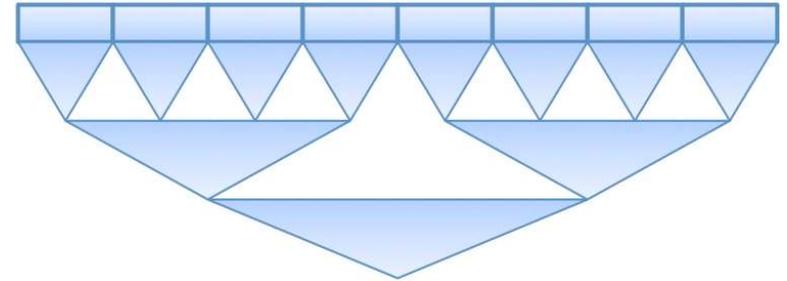

Parallel Reduction Tree for Commutative Operator

SIMD Utilization for Reduction Tree

Multistage reduction

- ▶ The local memory is usually limited (e.g. 50kB), which restricts the maximum size of the array that can be processed
- ▶ Therefore, for large arrays need to be processed in multiple stages
 - ▶ The result of a local memory reduction is stored in the array and then this array is reduced

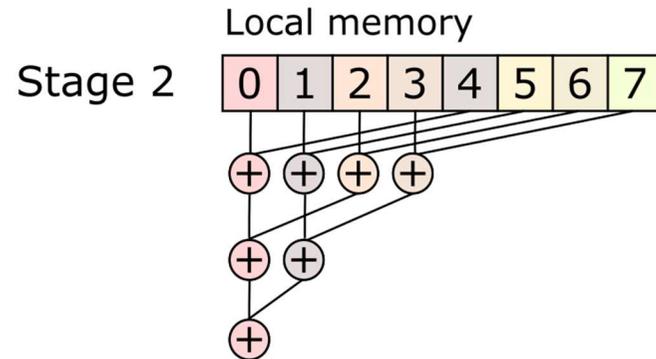

Two-stage reduction

Stage 1

Different colours denote different threads

Global memory

```
__kernel
void reduce(__global float* buffer,
            __local float* scratch,
            __const int length,
            __global float* result) {

    int global_index = get_global_id(0);
    float accumulator = INFINITY;
    // Loop sequentially over chunks of input
    vector
    while (global_index < length) {
        float element = buffer[global_index];
        accumulator = (accumulator < element) ?
accumulator : element;
        global_index += get_global_size(0);
    }

    // Perform parallel reduction
    [The same code as in the previous example]
}
```

- ▶ First stage: serial reduction by N concurrent threads
 - ▶ Number of threads $<$ data items
- ▶ Second stage: parallel reduction in local memory

Reduction execution times on CPU/GPU

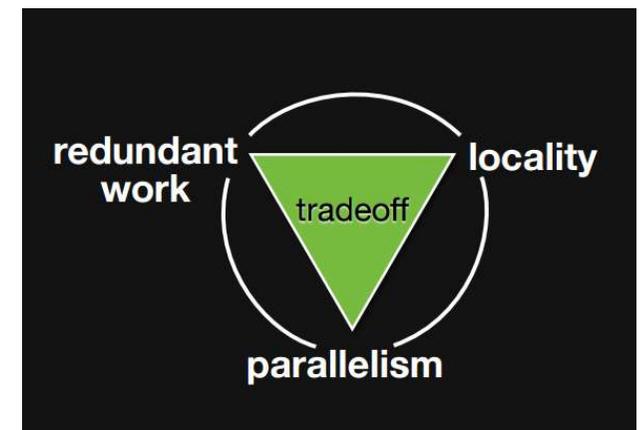

- ▶ Different reduction algorithm may be optimal for CPU and GPU
- ▶ This can also vary from one GPU to another
- ▶ The results from: <http://developer.amd.com/resources/articles-whitepapers/opencl-optimization-case-study-simple-reductions/>

Better way?

- ▶ **Halide** - a language for image processing and computational photography
 - ▶ <http://halide-lang.org/>
 - ▶ Code written in a high-level language, then translated to x86/SSE, ARM, CUDA, OpenCL
 - ▶ The optimization strategy defined separately as a *schedule*
 - ▶ Auto-tune software can test thousands of schedules and choose the one that is the best for a particular platform
 - ▶ (Semi-)automatically find the best trade-offs for a particular platform
 - ▶ Designed for image processing but similar languages created for other purposes

Advanced Graphics & Image Processing

Image-based rendering and Light fields

Part 1/4 – context, definition and technology

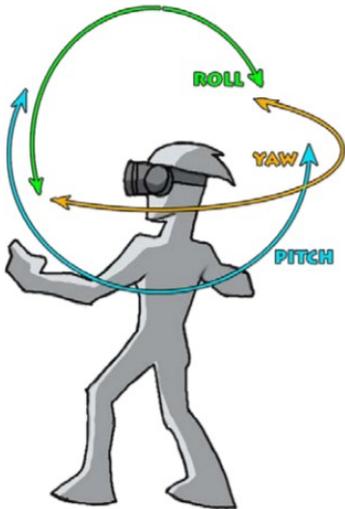

Rafał Mantiuk

Computer Laboratory, University of Cambridge

Motivation: 3DoF vs 6DoF in VR

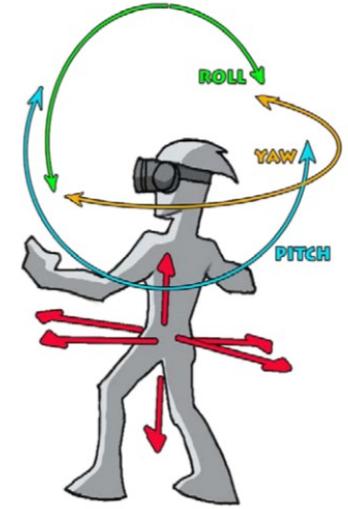

3DoF

- ▶ Tracking with inexpensive Inertial Measurements Units
- ▶ Content:
 - ▶ Geometry-based graphics
 - ▶ Omnidirectional stereo video
 - ▶ May induce cyber-sickness due to the lack of motion depth cues

6DoF

- ▶ Requires internal (inside-out) or external tracking
- ▶ Content:
 - ▶ Geometry-based graphics
 - ▶ Point-cloud rendering
 - ▶ Image-based rendering
 - ▶ View interpolation
 - ▶ **Light fields**
 - ▶ ...

3D computer graphics

- ▶ We need:
 - ▶ Geometry + materials + textures
 - ▶ Lights
- ▶ Full control of illumination, realistic material appearance
- ▶ Graphics assets are expensive to create
- ▶ Rendering is expensive
 - ▶ Shading tends to take most of the computation

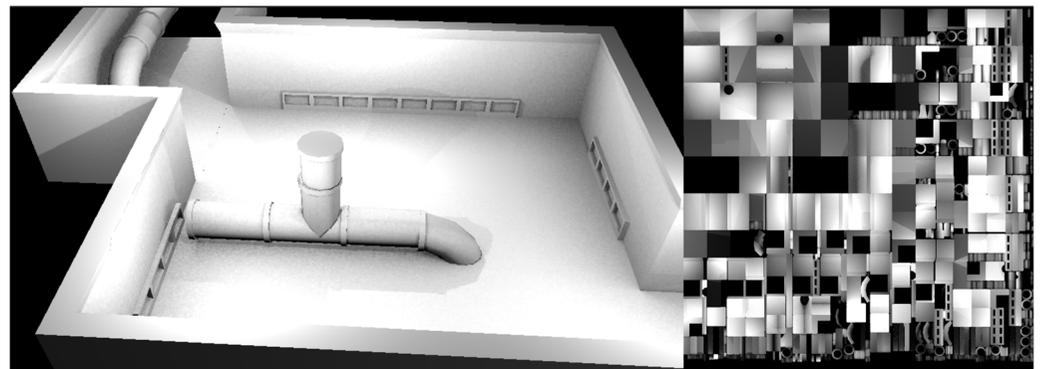

Cyberpunk 2077 (C) 2020 by CD Projekt RED

Baked / precomputed illumination

- ▶ We need:
 - ▶ Geometry + textures + (light maps)
- ▶ No need to scan and model materials
- ▶ Much faster rendering – simplified shading

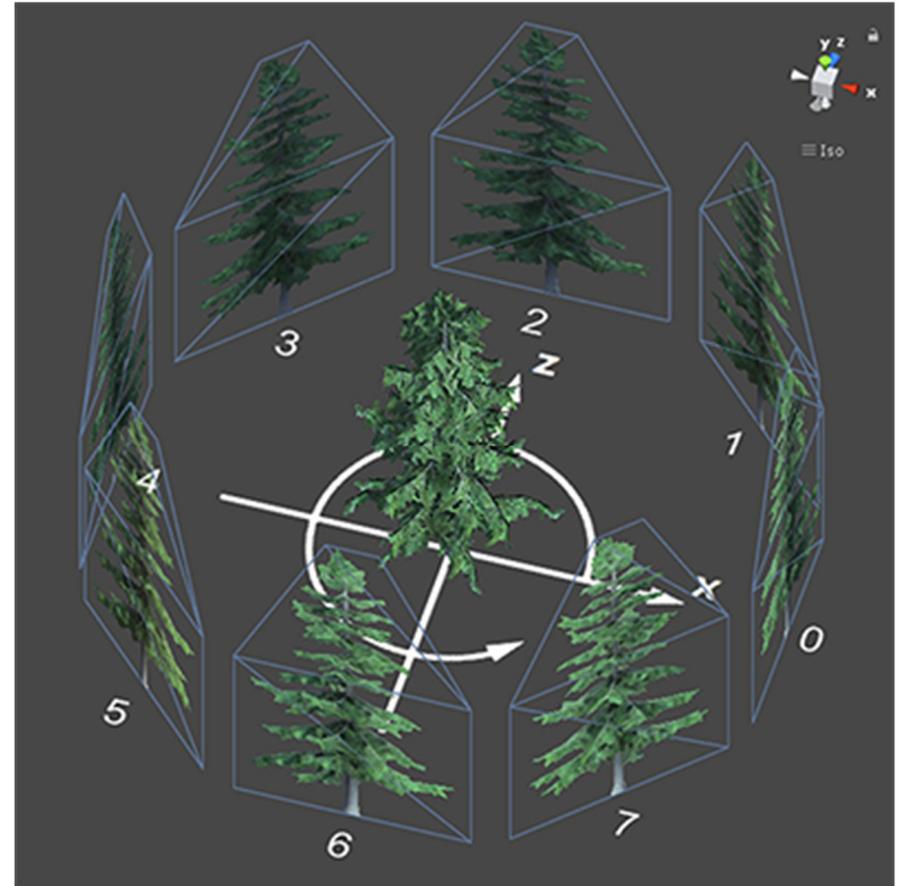

Google Earth

Precomputed light maps (from Wikipedia)

Billboards / Sprites

- ▶ **We need:**
 - ▶ Simplified geometry + textures (with alpha)
 - ▶ Lights
- ▶ **Much faster to render than objects with 1000s of triangles**
- ▶ **Used for distant objects**
 - ▶ or a small rendering budget
- ▶ **Can be pre-computed from complex geometry**

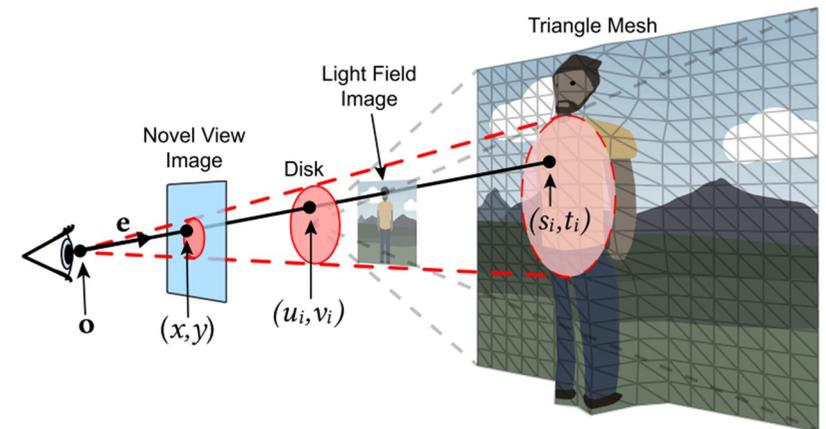

A tree rendered from a set of billboards

From:

<https://docs.unity3d.com/ScriptReference/BillboardAsset.html>

Light fields + depth

- ▶ We need:
 - ▶ Depth map
 - ▶ Images of the object/scene
 - ▶ Camera
- ▶ We can use camera-captured images
- ▶ View-dependent shading
- ▶ Depth-map can be computed using multi-view stereo techniques
 - ▶ CV methods can be unreliable
- ▶ No relighting

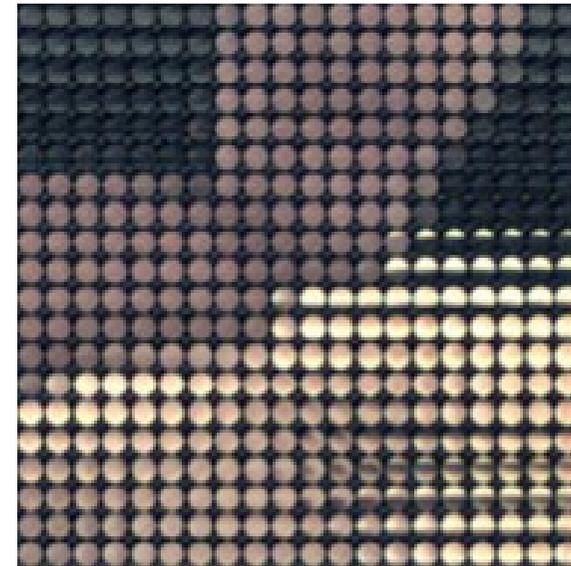

A depth map is approximated by triangle mesh and rasterized. From: Overbeck et al. TOG 2018, <https://doi.org/10.1145/3272127.3275031>.

Demo:
<https://augmentedperception.github.io/welcome-to-lightfields/>

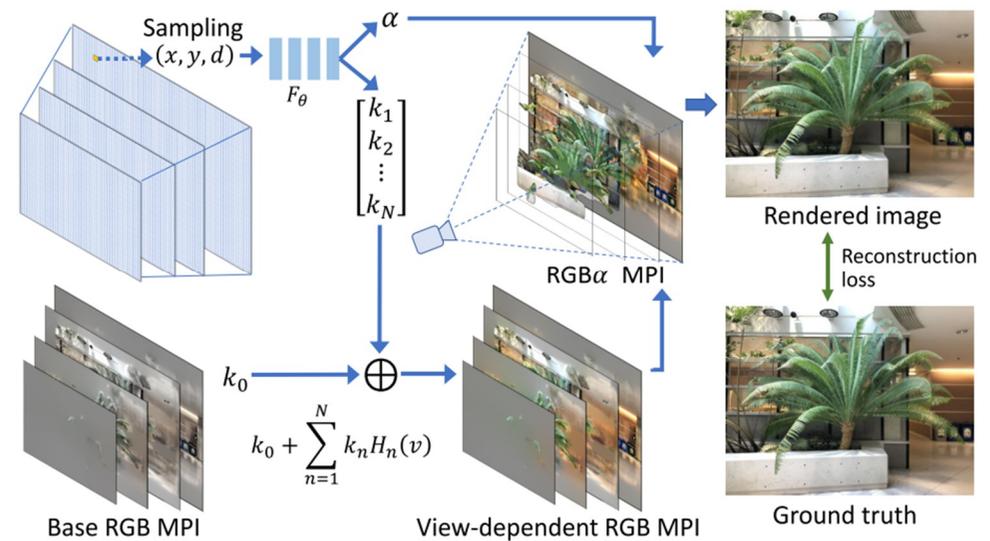

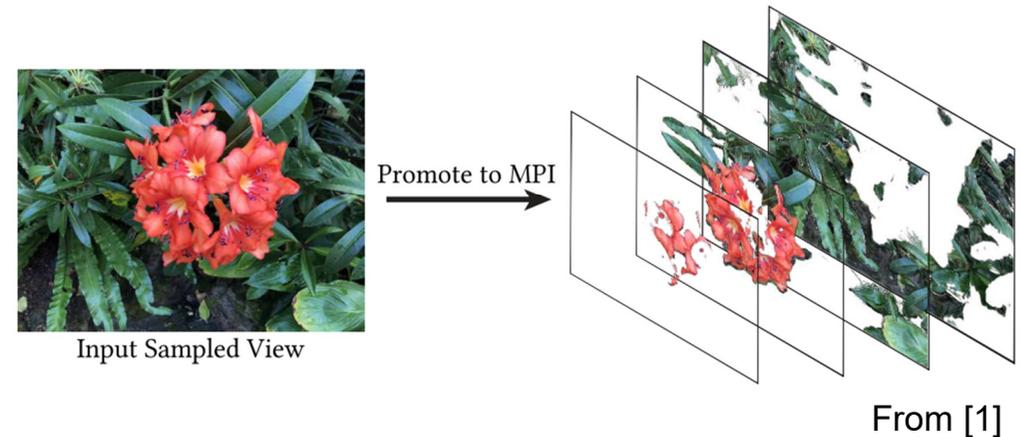

Light fields

- ▶ We need:
 - ▶ Images of the scene
 - ▶ Or a microlens image
 - ▶ Camera
- ▶ As light fields +depth but
 - ▶ No geometry, no need for any 3D reconstruction
 - ▶ Photographs are re-projected on the plane
 - ▶ Requires massive number of images for good quality

Multi-plane images (MPI)

- ▶ We need:
 - ▶ Images of the scene + camera poses
- ▶ Each plane: RGB + alpha
 - ▶ Decomposition formulated as an optimization problem
 - ▶ Differential rendering
- ▶ Only front view

<https://nex-mpi.github.io/>

From [2]

Neural Radiance Fields (NeRF)

- ▶ We need
 - ▶ Images of the scene + camera poses
 - ▶ Similar to MPI but stored in a volumetric data structure
 - ▶ Implicit: multi-layer perceptron
 - ▶ Explicit: Voxel grid
 - ▶ Volumetric differential rendering

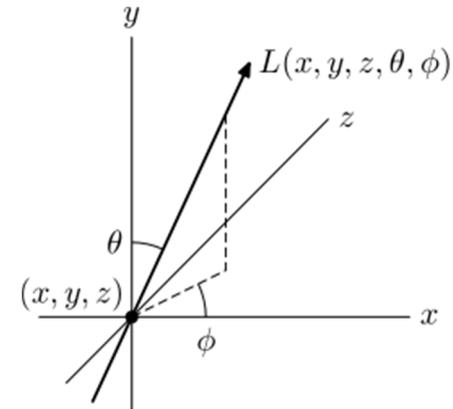

[1] Mildenhall, et al. “NeRF: Representing Scenes as Neural Radiance Fields for View Synthesis,” 405–21, 2020. https://doi.org/10.1007/978-3-030-58452-8_24.

[2] Yu et al. “Plenoxels: Radiance Fields without Neural Networks.” In *CVPR*, 5501–10, 2022. <http://arxiv.org/abs/2112.05131>.

From a plenoptic function to a light field

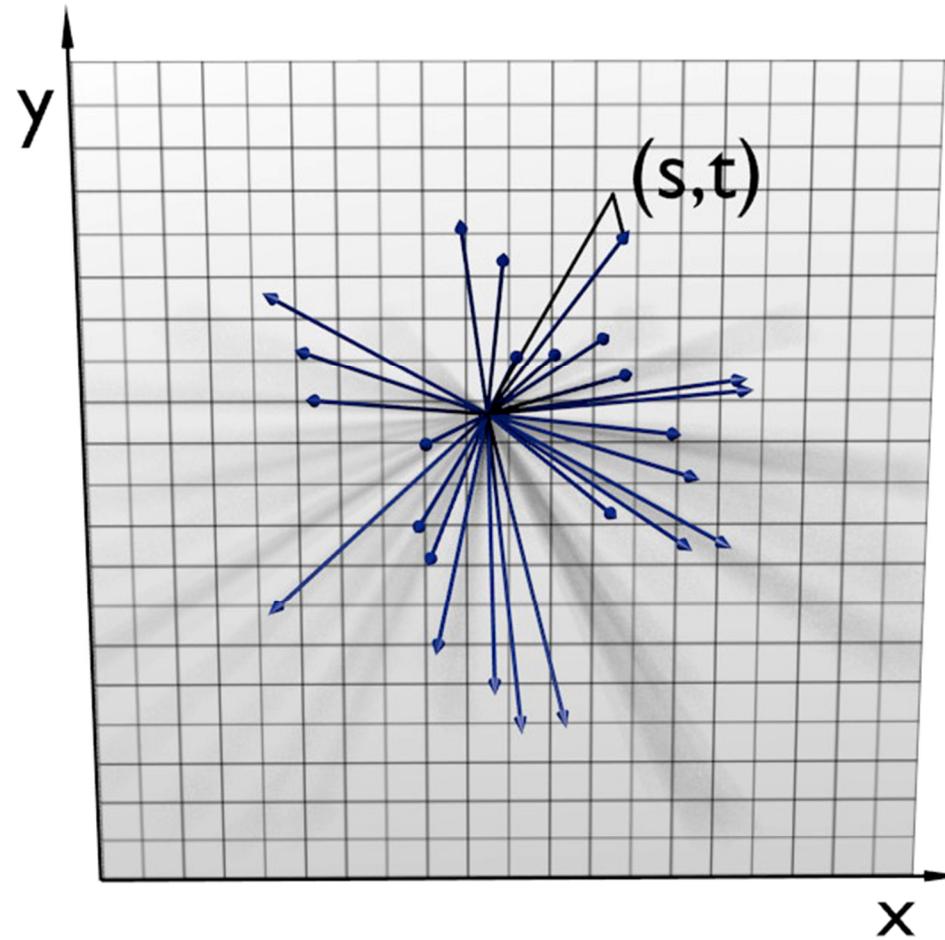

- ▶ Plenoptic function – describes all possible rays in a 3D space

- ▶ Function of position (x, y, z) and ray direction (θ, ϕ)
- ▶ But also wavelength λ and time t
- ▶ Between 5 and 7 dimensions

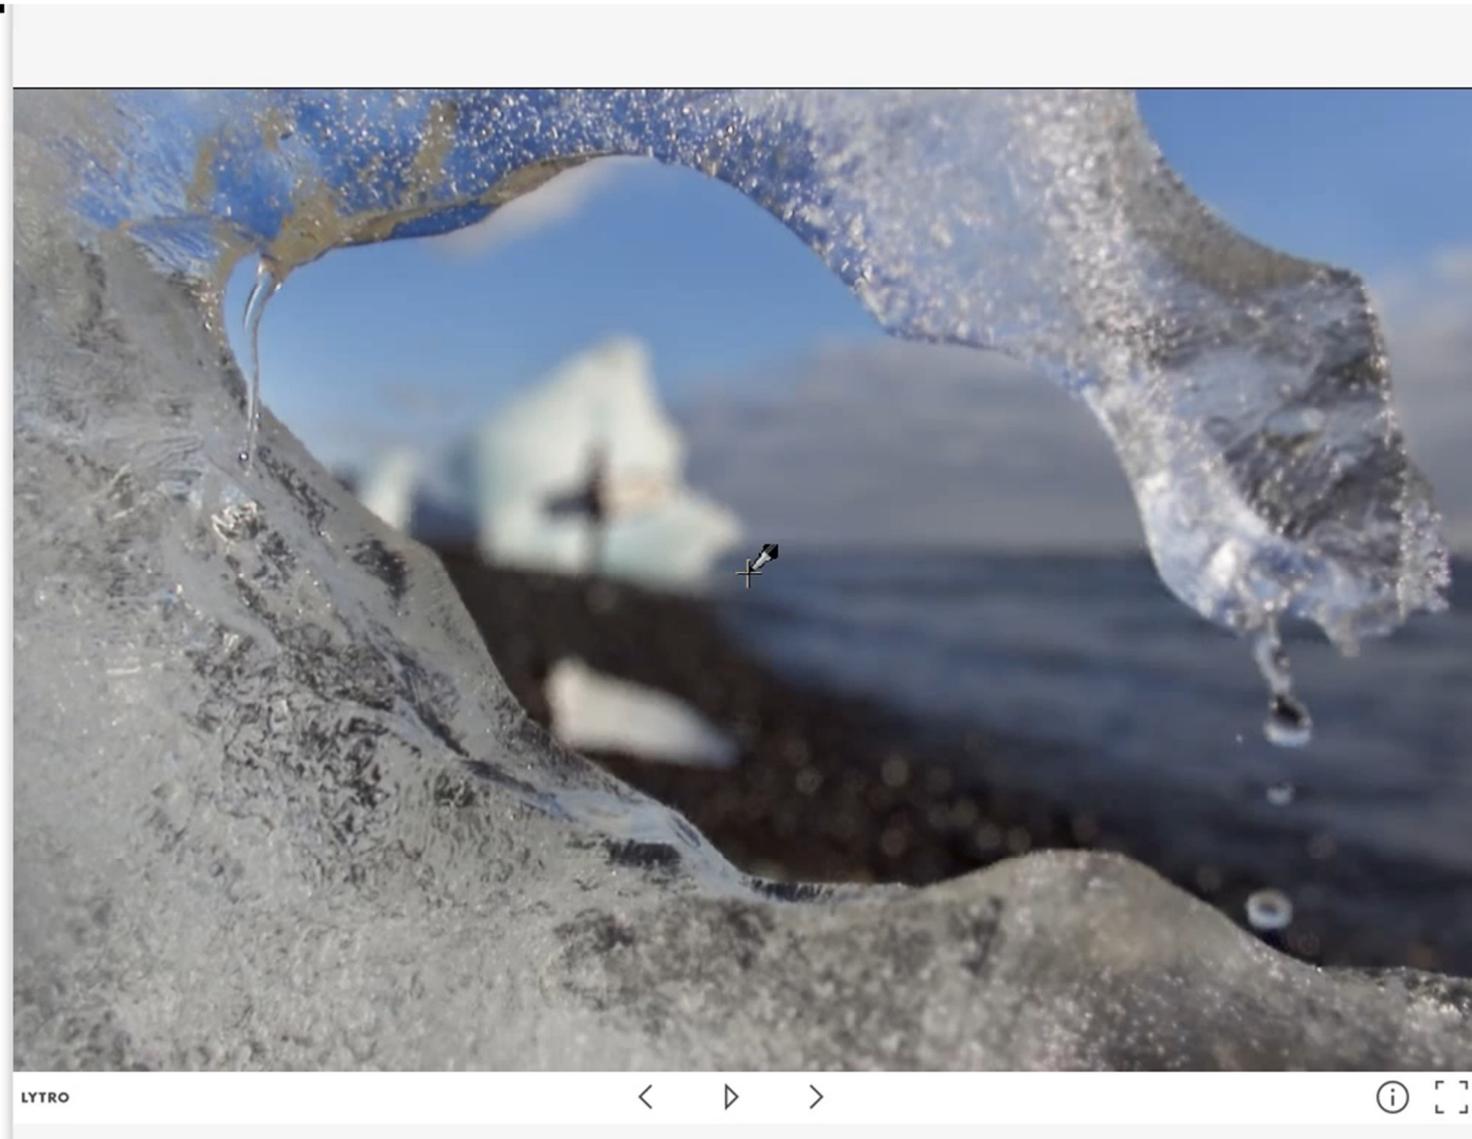

- ▶ But the number of dimensions can be reduced if
 - ▶ The camera stays outside the convex hull of the object
 - ▶ The light travels in uniform medium
 - ▶ Then, radiance L remains the same along the ray (until the ray hits an object)
 - ▶ This way we obtain a **4D light field**

Planar 4D light field

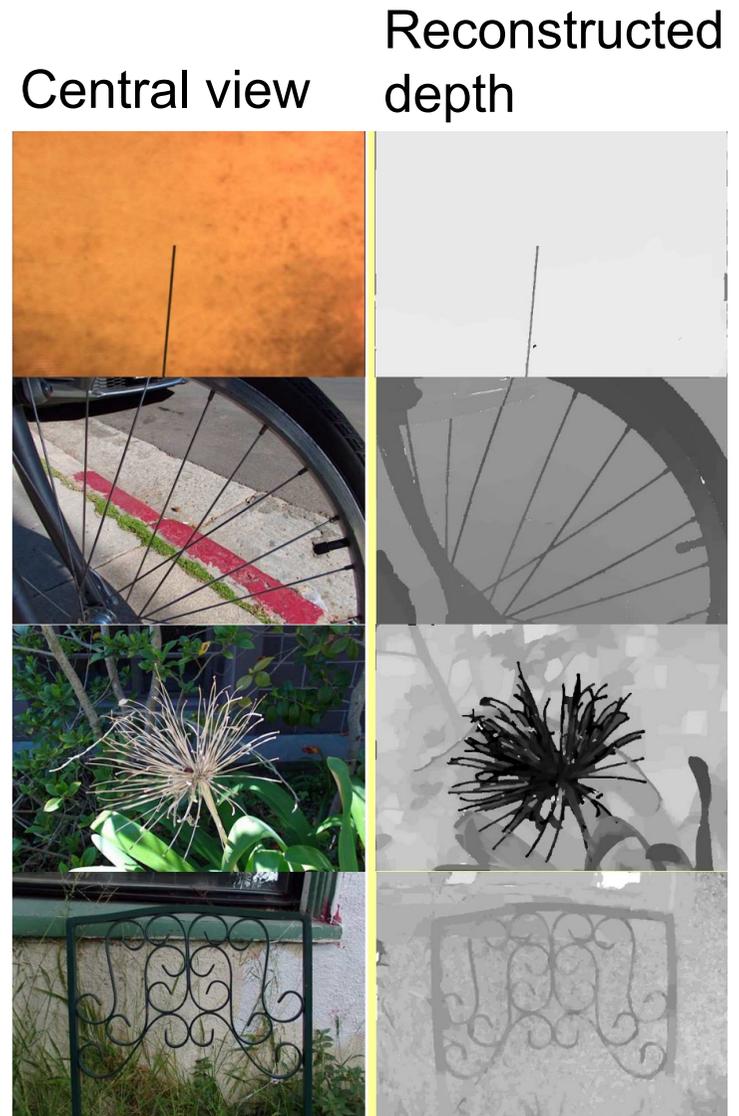

Refocusing and view point adjustment

Depth estimation from light field

- ▶ Passive sensing of depth
- ▶ Light field captures multiple depth cues
 - ▶ Correspondance (disparity) between the views
 - ▶ Defocus
 - ▶ Occlusions

From: *Ting-Chun Wang, Alexei A. Efros, Ravi Ramamoorthi*; The IEEE International Conference on Computer Vision (ICCV), 2015, pp. 3487-3495

Two methods to capture light fields

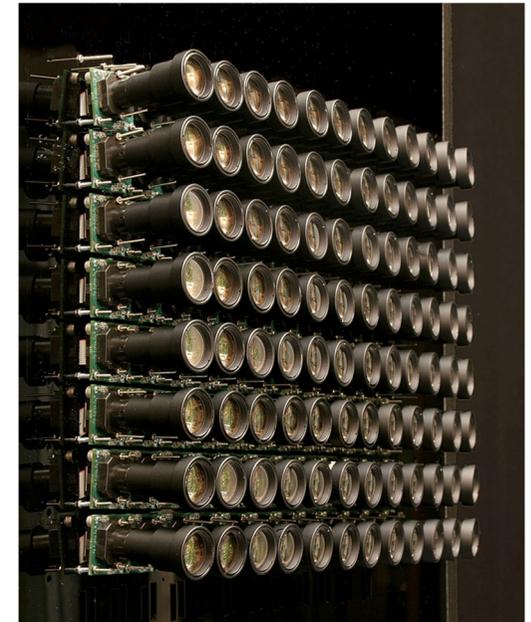

Micro-lens array

- ▶ Small baseline
- ▶ Good for digital refocusing
- ▶ Limited resolution

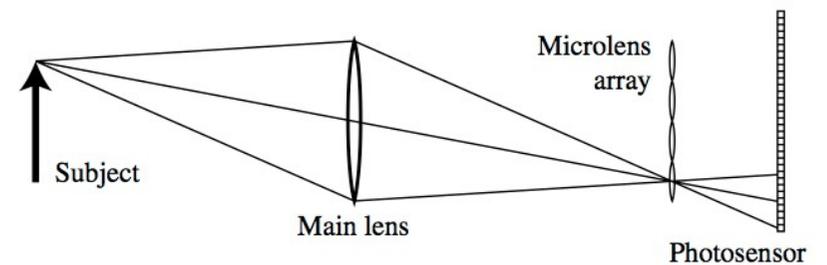

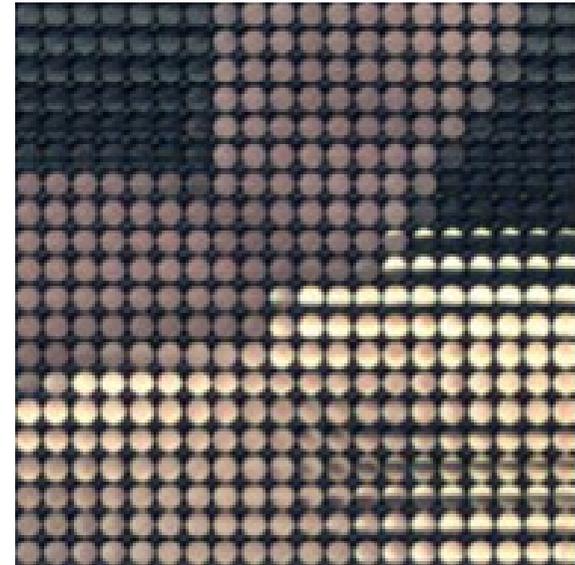

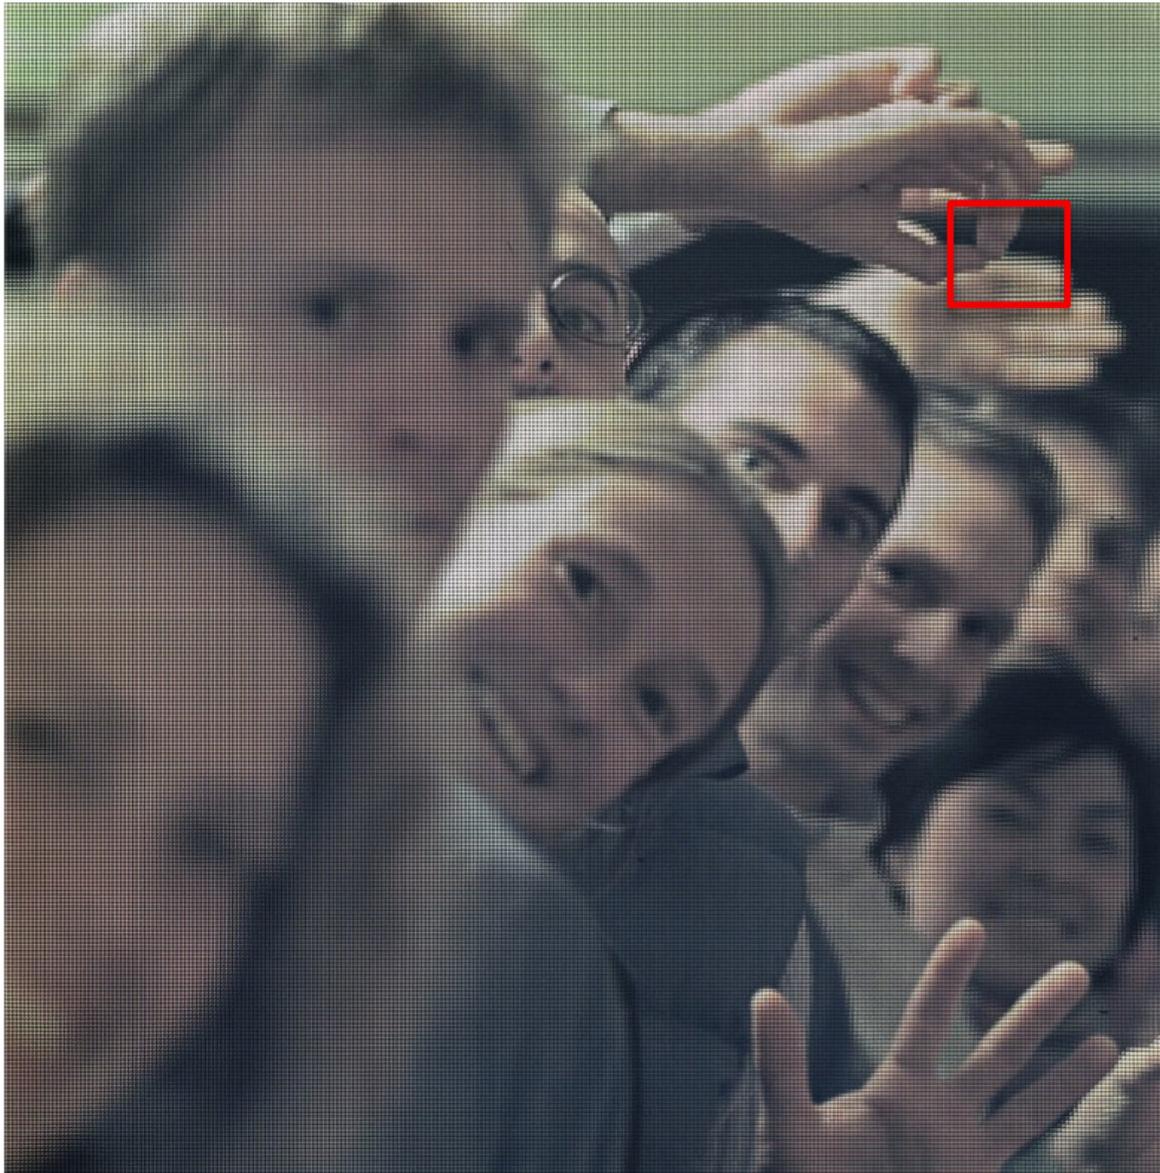

Camera array

- ▶ Large baseline
- ▶ High resolution
- ▶ Rendering often requires approximate depth

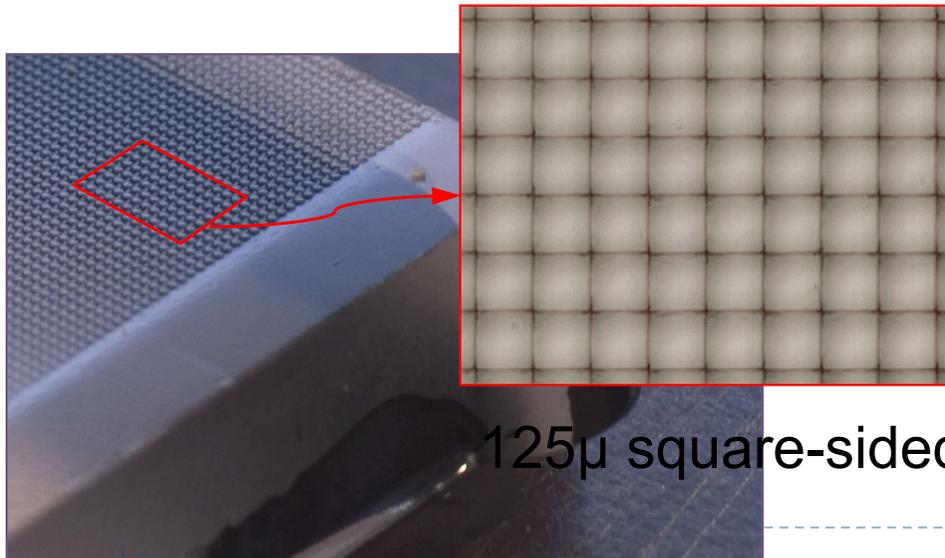

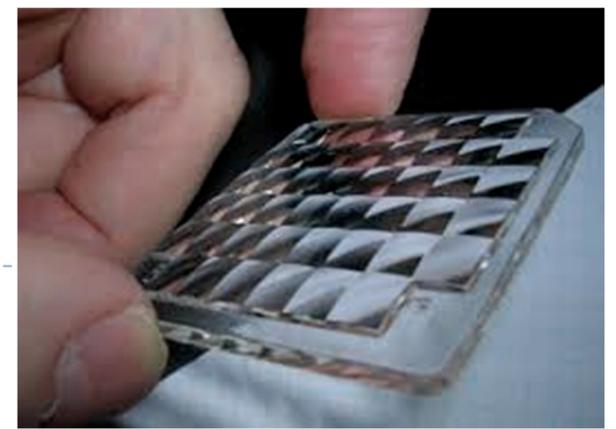

Light field image – with microlens array

Digital Refocusing using Light Field Camera

Lenslet array

Light fields

Part 2/4 – imaging and lens

Rafał Mantiuk

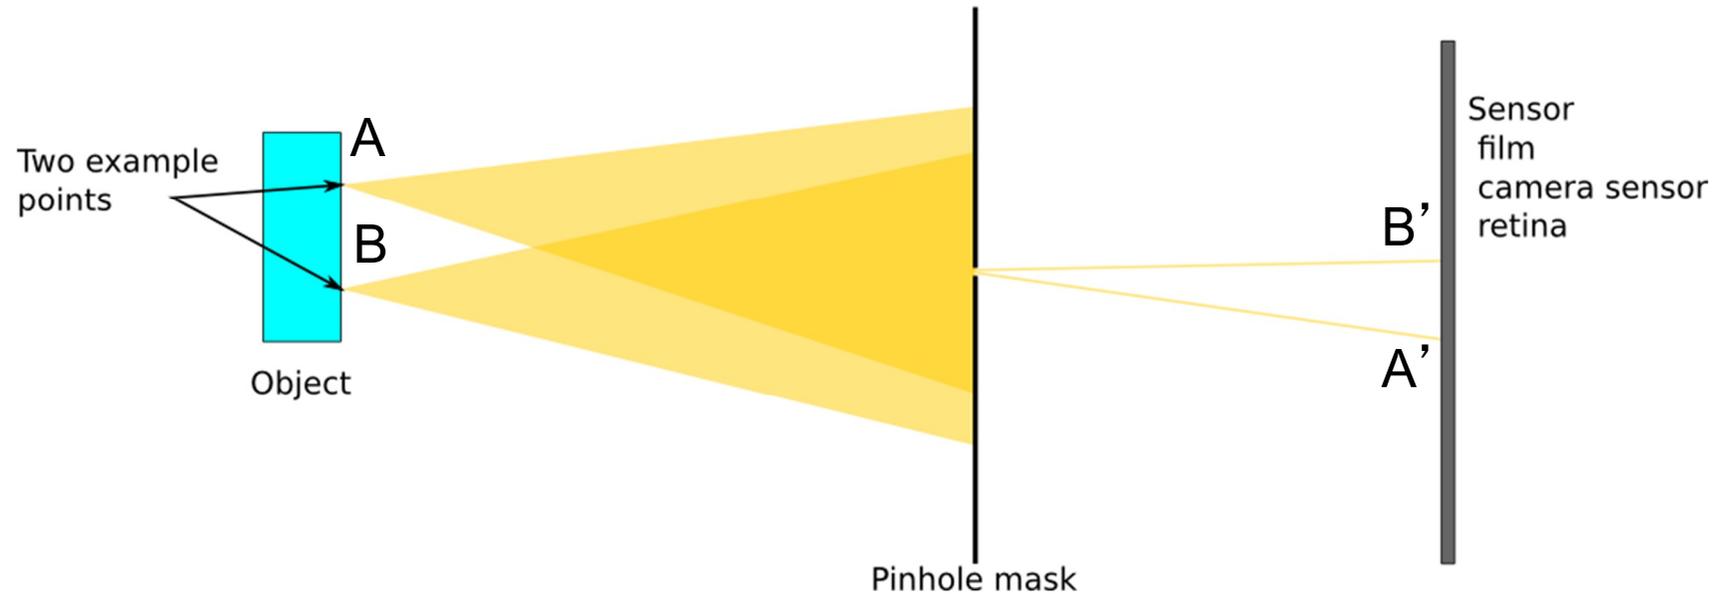

Computer Laboratory, University of Cambridge

Imaging – without lens

Every point in the scene illuminates every point (pixel) on a sensor. Everything overlaps - no useful image.

Imaging – pinhole camera

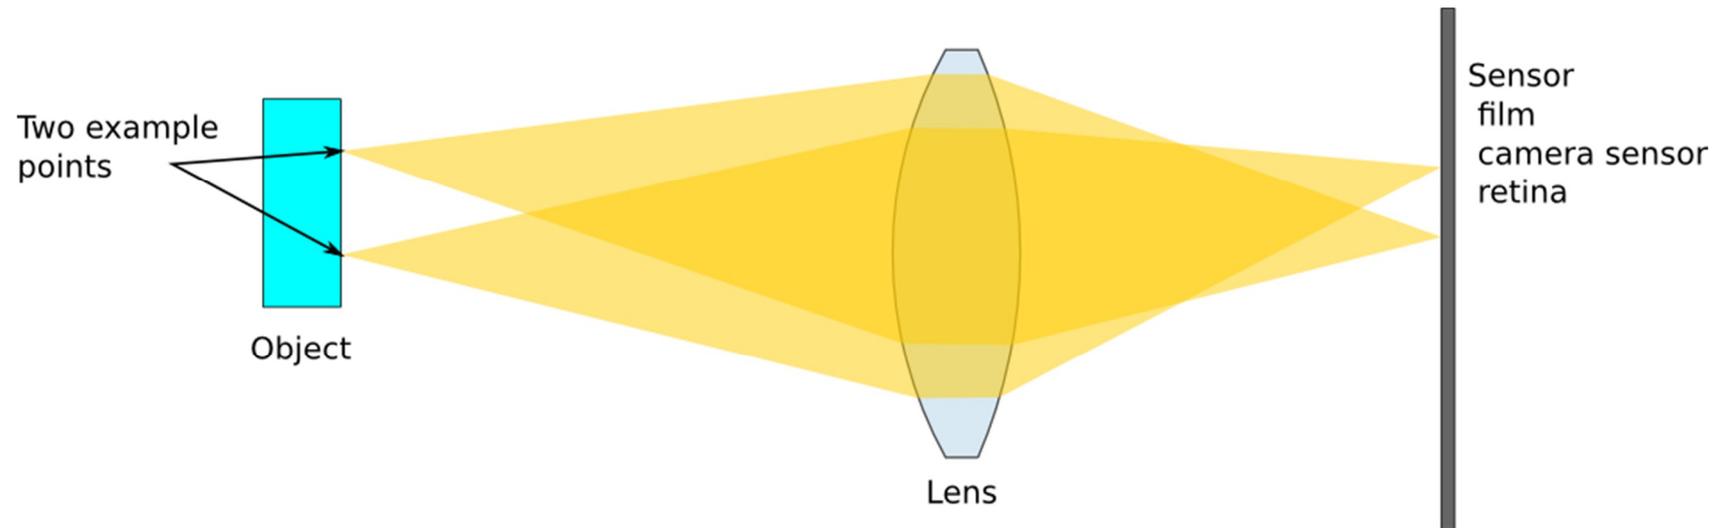

Pinhole masks all but only tiny beams of light. The light from different points is separated and the image is formed.

But very little light reaches the sensor.

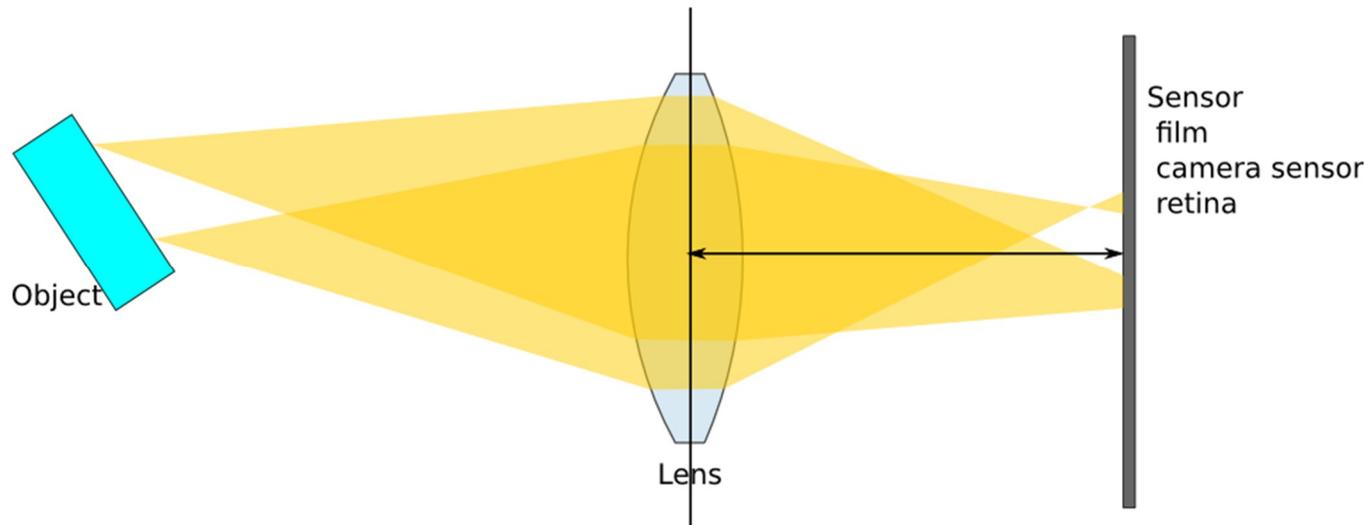

Imaging – lens

Lens can focus a beam of light on a sensor (focal plane).

Much more light-efficient than the pinhole.

Imaging – lens

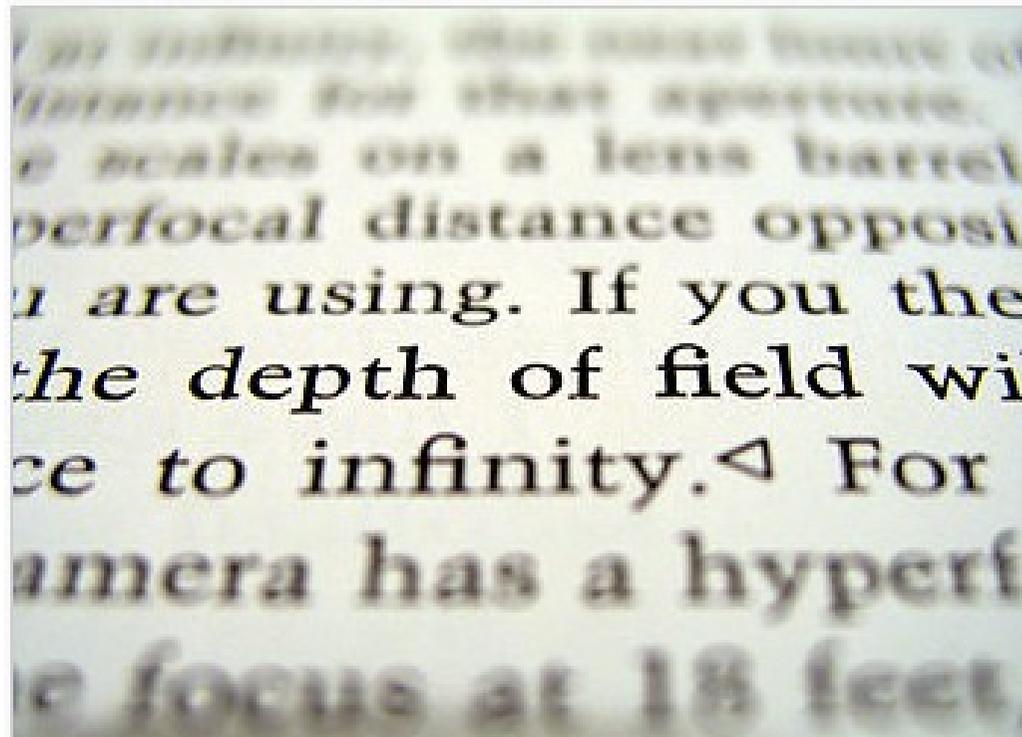

But if the light beams coming from different distances are not focused on the same plane.

These points will appear blurry in the resulting image.

Camera needs to move lens to focus an image on the sensor.

Depth of field

- ▶ Depth of field – range of depths that provides sufficient focus

Defocus blur is often desirable

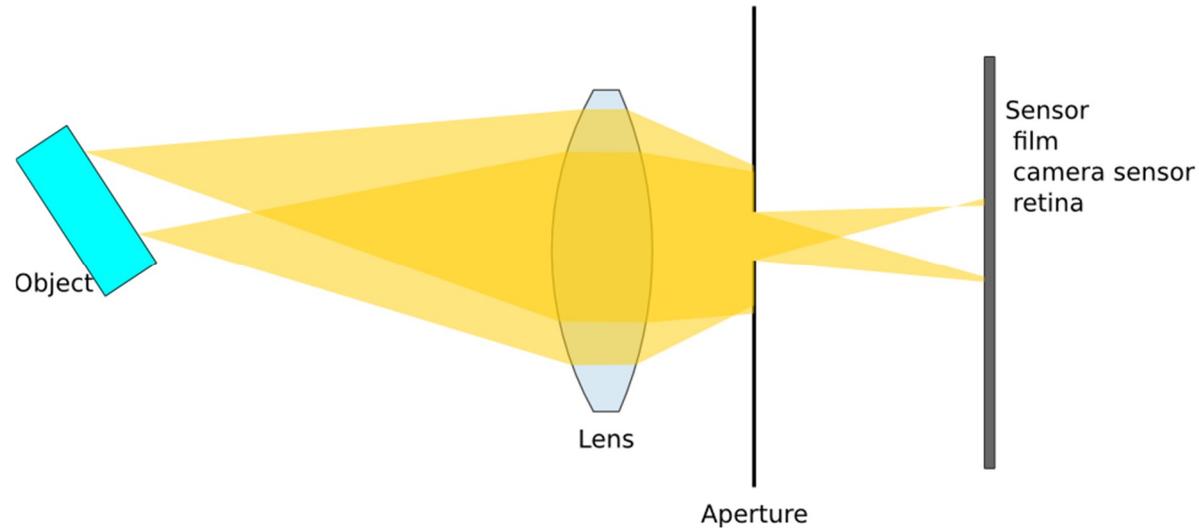

To separate the object of interest from background

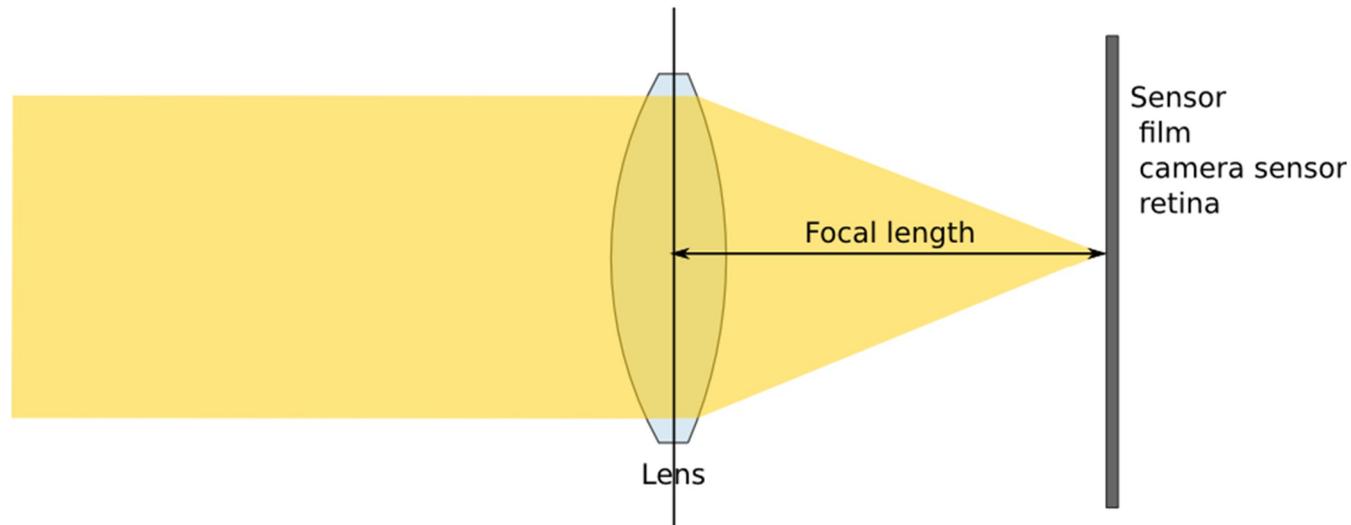

Defocus blur is a strong depth cue

Imaging – aperture

Aperture (introduced behind the lens) reduces the amount of light reaching sensor, but it also reduces blurriness from defocus (increases depth-of-field).

Imaging – lens

Focal length – length between the sensor and the lens that is needed to focus light coming from an infinite distance.

Larger focal length of a lens – more or less magnification?

Light fields

Part 4/4 – light field rendering

Rafał Mantiuk

Computer Laboratory, University of Cambridge

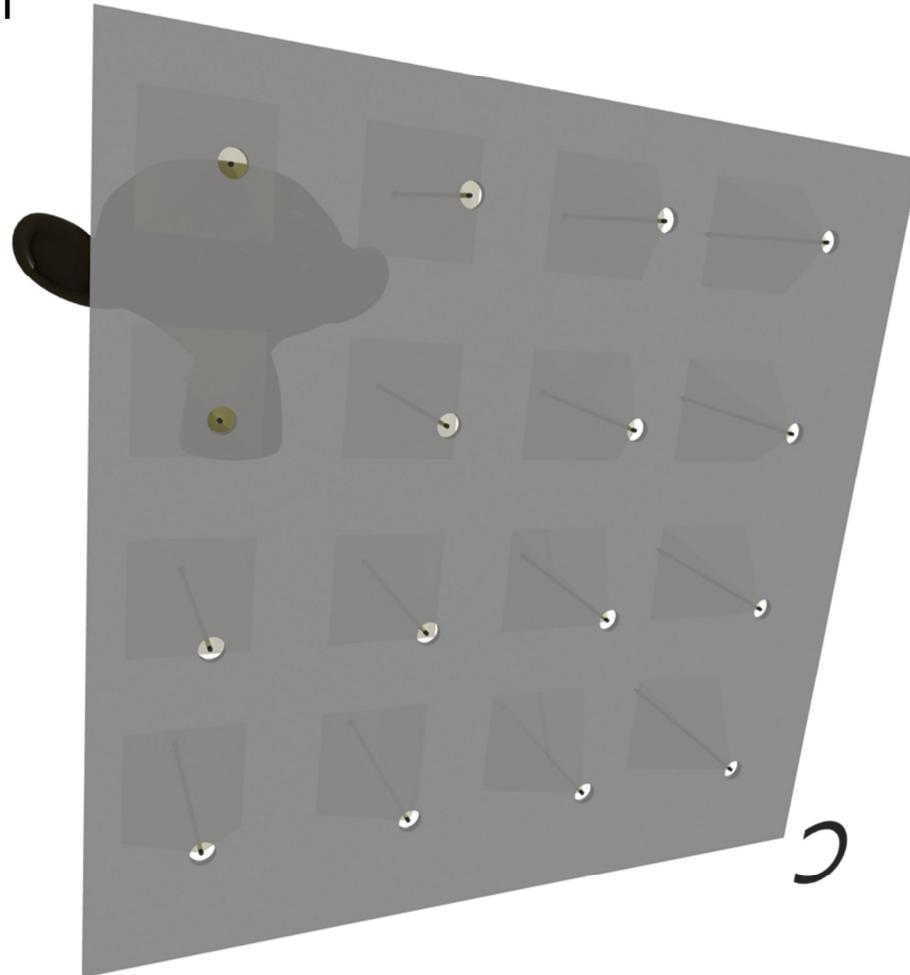

Light field rendering (1/3)

We want to render a scene (Blender monkey) as seen by camera K. We have a light field captured by a camera array. Each camera in the array has its aperture on plane C.

Light field rendering (2/3)

From the view point of camera K

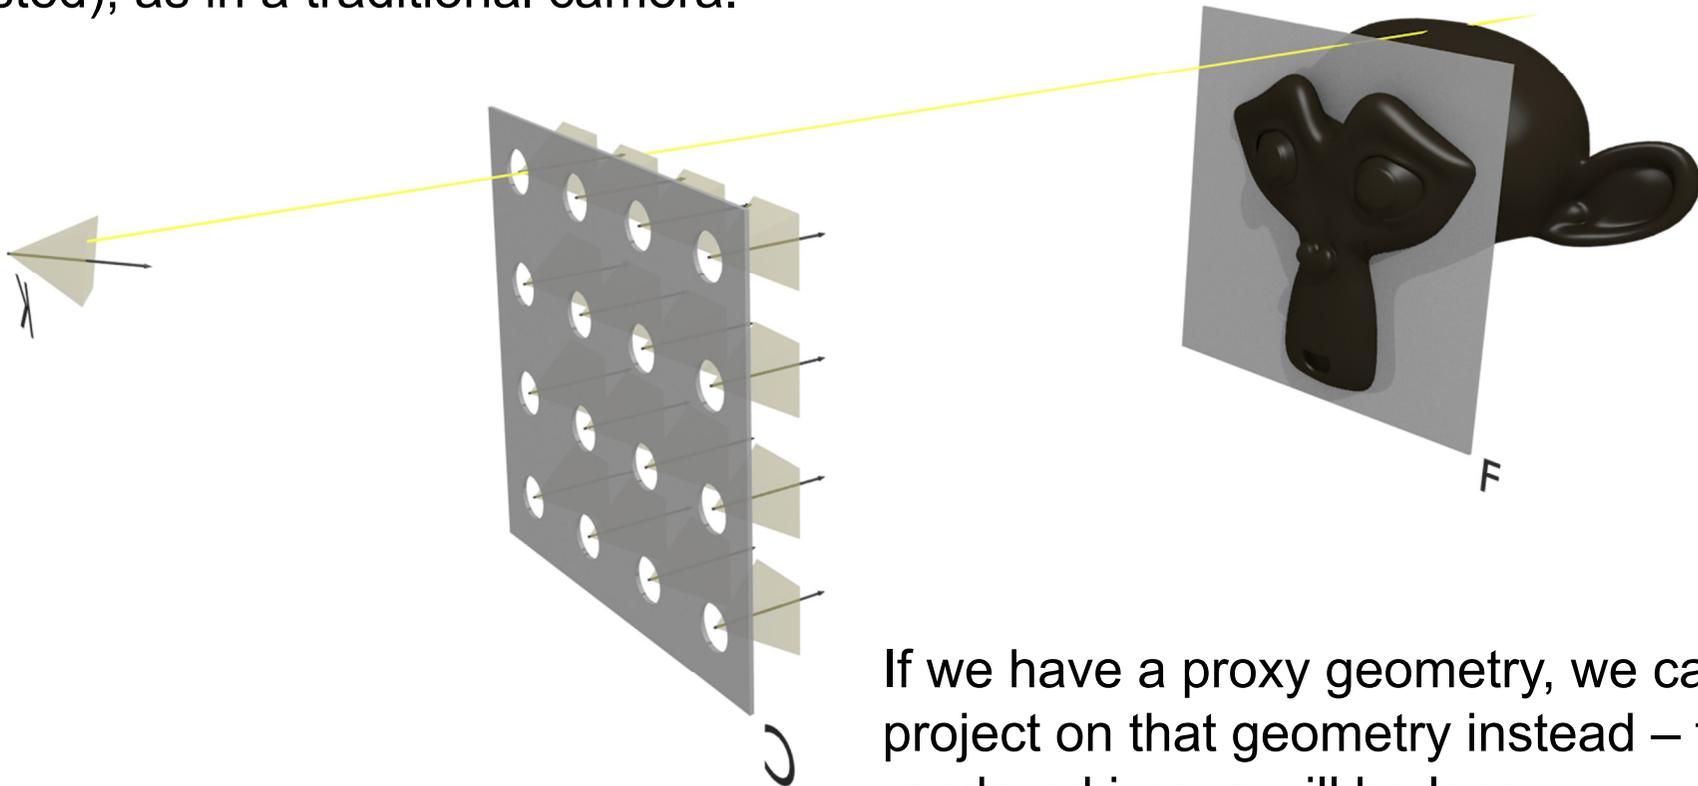

Each camera in the array provides accurate light measurements only for the rays originating from its pinhole aperture.

The missing rays can be either interpolated (reconstructed) or ignored.

Light field rendering (3 / 3)

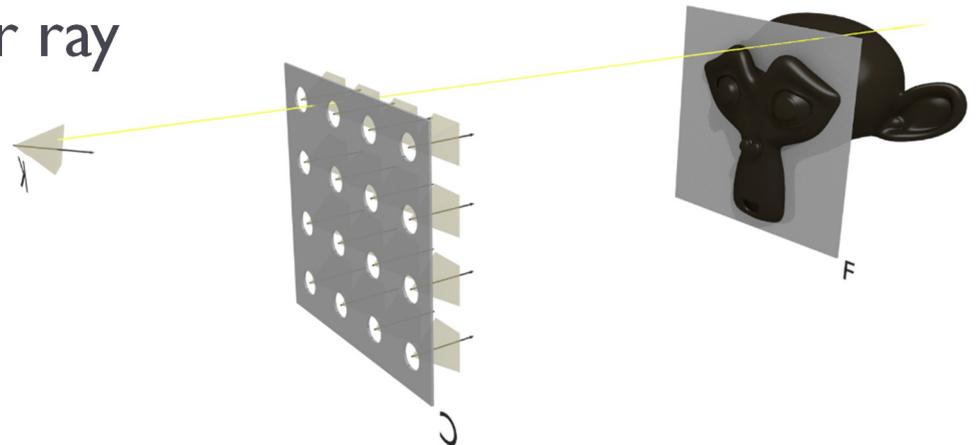

The rays from the camera need to be projected on the focal plane F. The objects on the focal plane will be sharp, and the objects in front or behind that plane will be blurry (ghosted), as in a traditional camera.

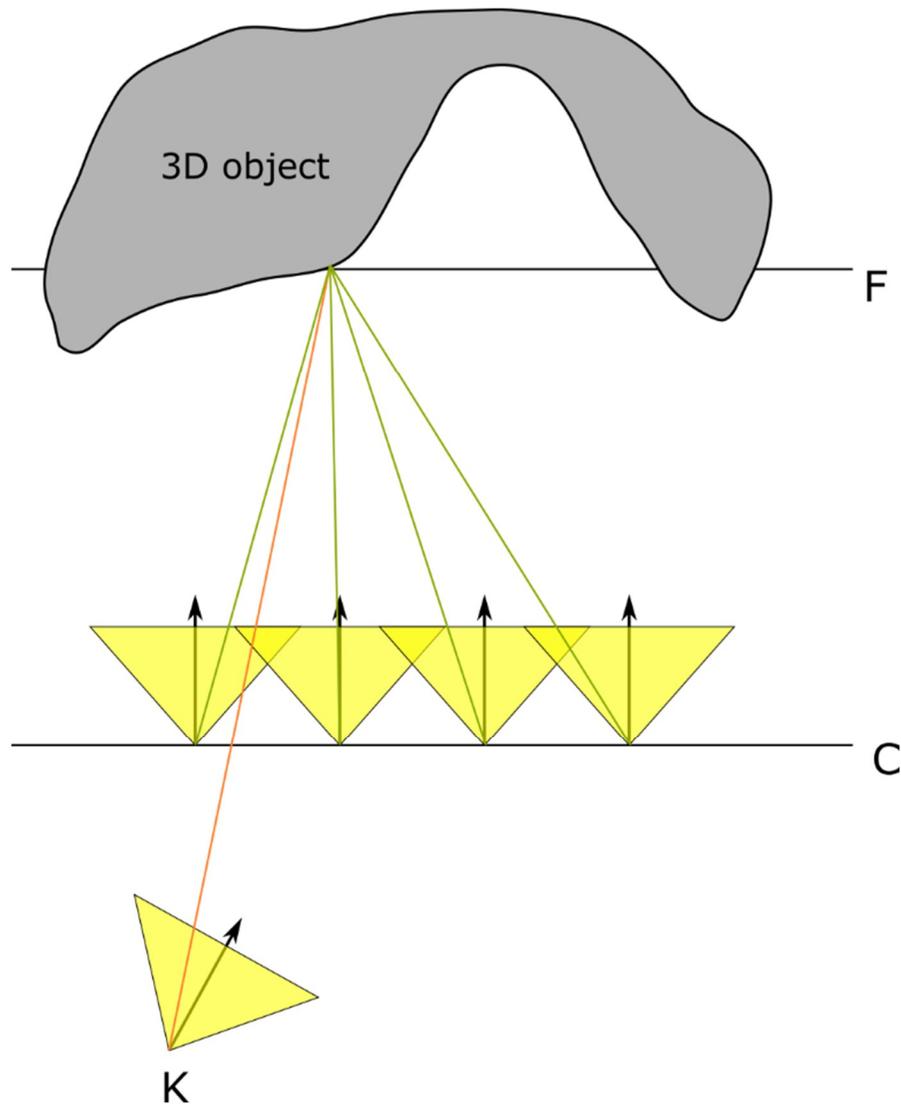

If we have a proxy geometry, we can project on that geometry instead – the rendered image will be less ghosted/blurry

Intuition behind light field rendering

- ▶ For large virtual aperture (use all cameras in the array)
 - ▶ Each camera in the array captures the scene
 - ▶ Then, each camera projects its image on the focal plane F
 - ▶ The virtual camera K captures the projection
- ▶ For small virtual aperture (pinhole)
 - ▶ For each ray from the virtual camera
 - ▶ interpolate rays from 4 nearest camera images
 - ▶ Or use the nearest-neighbour ray

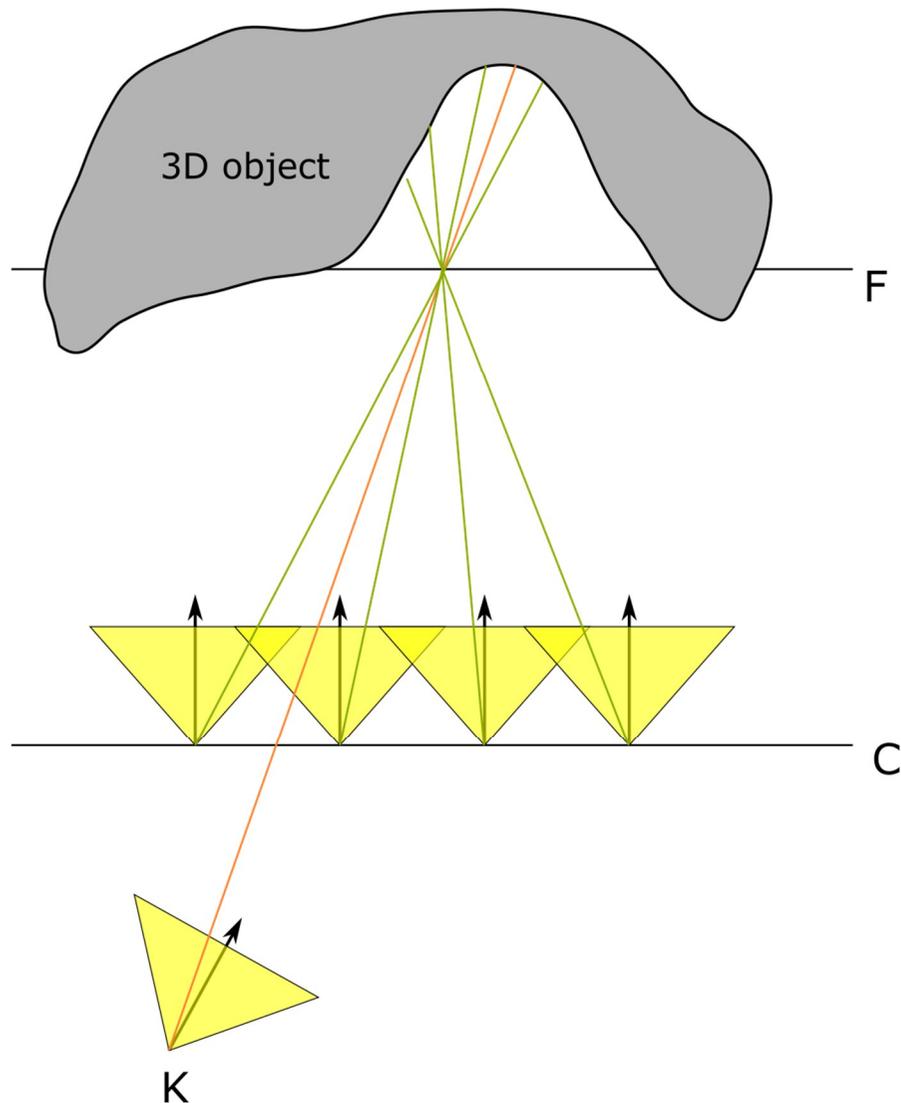

LF rendering – focal plane

- ▶ For a point on the focal plane, all cameras capture the same point on the 3D object
- ▶ They also capture approximately the same colour (for diffuse objects)
- ▶ Averaged colour will be the colour of the point on the surface

LF rendering – focal plane

- ▶ If the 3D object does not lie on the focal plane, all cameras capture different points on the object
- ▶ Averaging colour values will produce a „ghosted” image
- ▶ If we had unlimited number of cameras, this would produce a depth-of-field effect

Finding homographic transformation 1/3

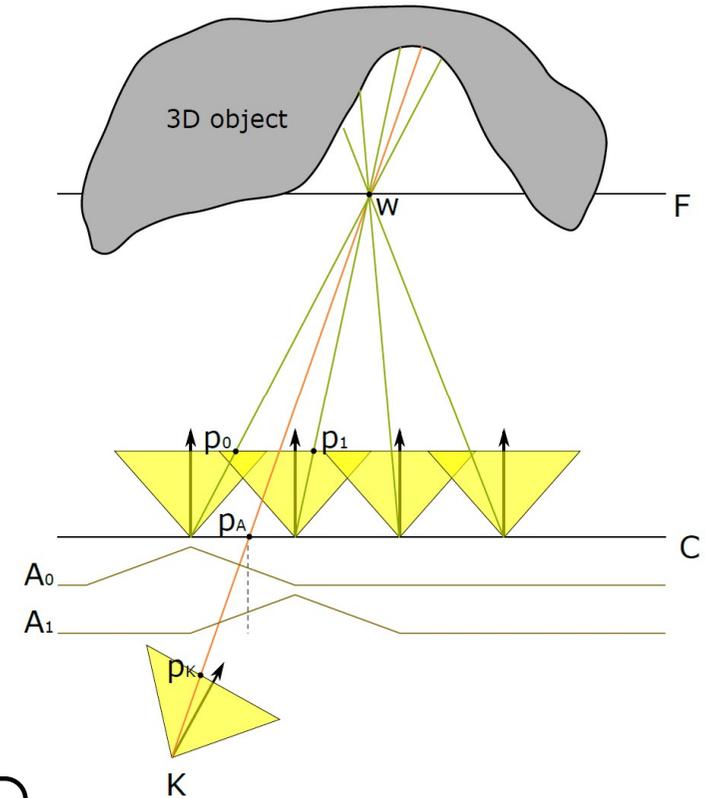

- ▶ For the pixel coordinates p_k of the virtual camera K, we want to find the corresponding coordinates p_i in the camera array image
- ▶ Given the world 3D coordinates of a point w :

$$p_i = K P V_i w$$

Intrinsic camera matrix

Projection matrix

View matrix

$$\begin{bmatrix} x_i \\ y_i \\ w_i \end{bmatrix} = \begin{bmatrix} f_x & 0 & c_x \\ 0 & f_y & c_y \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \end{bmatrix} \begin{bmatrix} v_{11} & v_{12} & v_{13} & v_{14} \\ v_{21} & v_{22} & v_{23} & v_{24} \\ v_{31} & v_{32} & v_{33} & v_{34} \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} X \\ Y \\ Z \\ 1 \end{bmatrix}$$

Finding homographic transformation 2/3

- ▶ A homography between two views is usually found as:

$$\begin{aligned}\mathbf{p}_K &= \mathbf{K}_K \mathbf{P} \mathbf{V}_K \mathbf{w} \\ \mathbf{p}_i &= \mathbf{K}_i \mathbf{P} \mathbf{V}_i \mathbf{w}\end{aligned}$$

hence

$$\mathbf{p}_i = \mathbf{K}_i \mathbf{P} \mathbf{V}_i \mathbf{V}_K^{-1} \mathbf{P}^{-1} \mathbf{K}_K^{-1} \mathbf{p}_K$$

- ▶ But, $\mathbf{K}_K \mathbf{P} \mathbf{V}_K$ is not a square matrix and cannot be inverted
 - ▶ To find the correspondence, we need to constrain 3D coordinates \mathbf{w} to lie on the plane:

$$\mathbf{N} \cdot (\mathbf{w} - \mathbf{w}_F) = 0 \quad \text{or} \quad d = [n_x \quad n_y \quad n_z \quad -\mathbf{N} \cdot \mathbf{w}_F] \begin{bmatrix} X \\ Y \\ Z \\ 1 \end{bmatrix}$$

Finding homographic

The plane in the camera coordinates (not world coordinates)

3/3

- ▶ Then, we add the plane equation to the projection matrix

$$\begin{bmatrix} x_i \\ y_i \\ d_i \\ w_i \end{bmatrix} = \begin{bmatrix} f_x & 0 & 0 & c_x \\ 0 & f_y & 0 & c_y \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ n_x^{(c)} & n_y^{(c)} & n_z^{(c)} & -N^{(c)} \cdot w_F^{(c)} \\ 0 & 0 & 1 & 0 \end{bmatrix} \begin{bmatrix} v_{11} & v_{12} & v_{13} & v_{14} \\ v_{21} & v_{22} & v_{23} & v_{24} \\ v_{31} & v_{32} & v_{33} & v_{34} \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} X \\ Y \\ Z \\ 1 \end{bmatrix}$$

\hat{p}_i \hat{K}_i \hat{P} V_i w

- ▶ Where d_i is the distance to the plane (set to 0)
- ▶ Hence

$$\hat{p}_i = \hat{K}_i \hat{P} V_i V_K^{-1} \hat{P}^{-1} \hat{K}_K^{-1} p_K$$

Colour perception and colour spaces

Part 1/5 – physics of light

Rafał Mantiuk

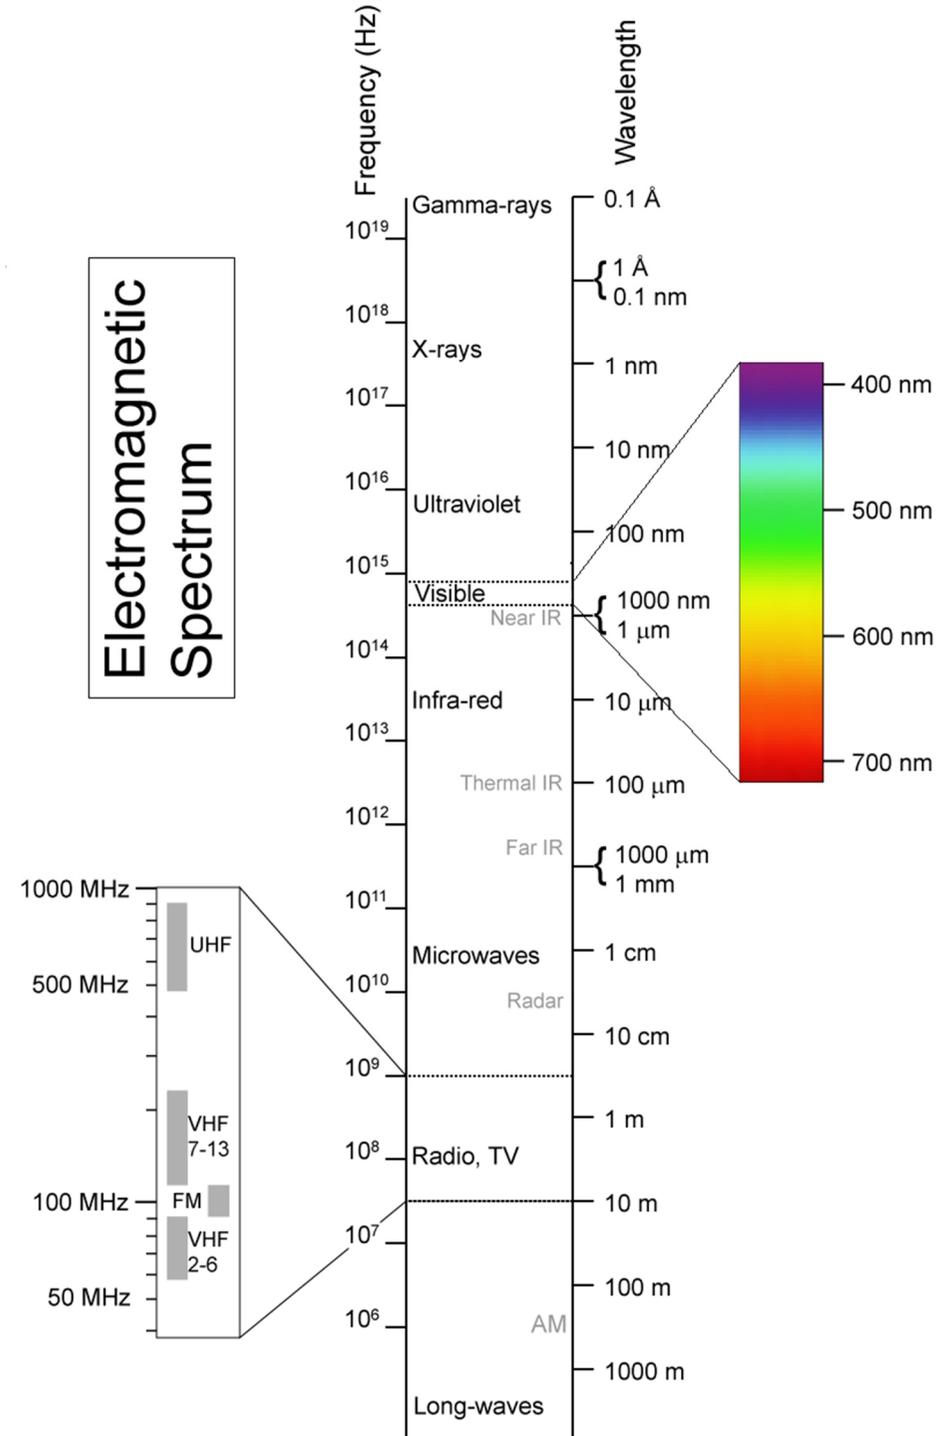

Computer Laboratory, University of Cambridge

Electromagnetic spectrum

▶ Visible light

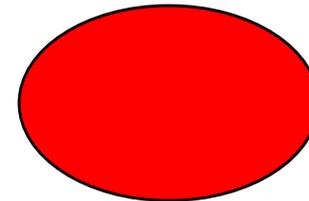

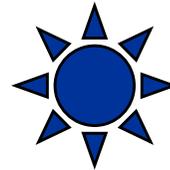

- ▶ Electromagnetic waves of wavelength in the range 380nm to 730nm
- ▶ Earth's atmosphere lets through a lot of light in this wavelength band
- ▶ Higher in energy than thermal infrared, so heat does not interfere with vision

Colour

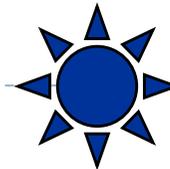

- ▶ There is no physical definition of colour – colour is the result of our perception
- ▶ For reflective displays / objects

colour = perception(illumination × reflectance)

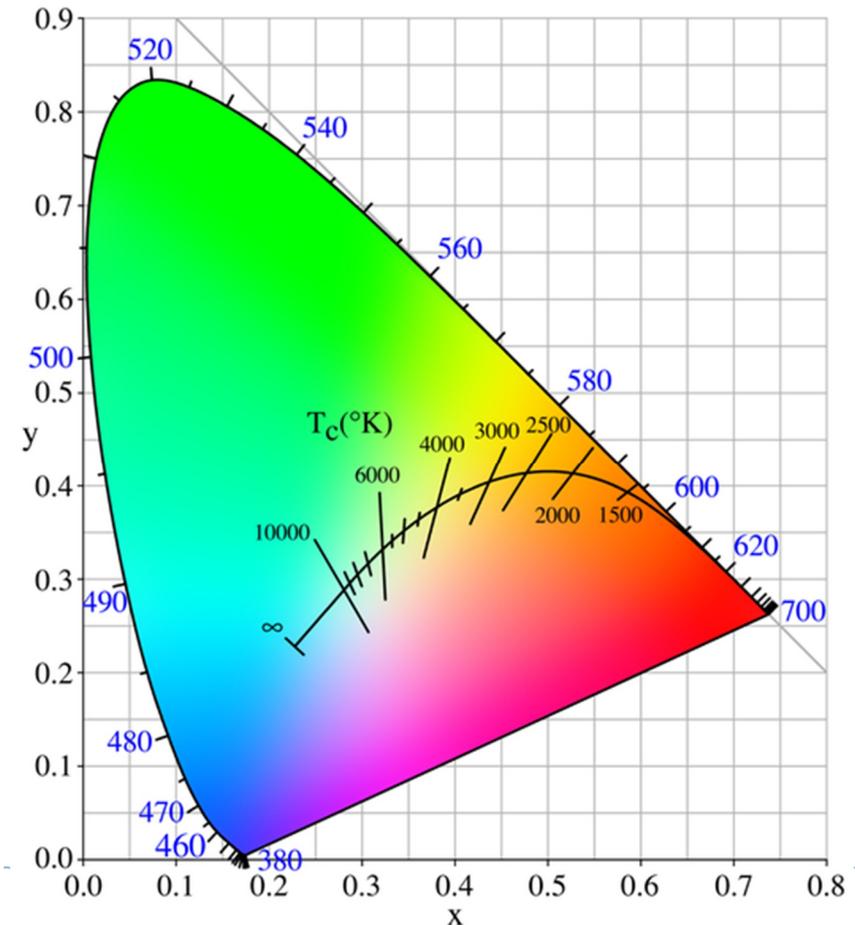

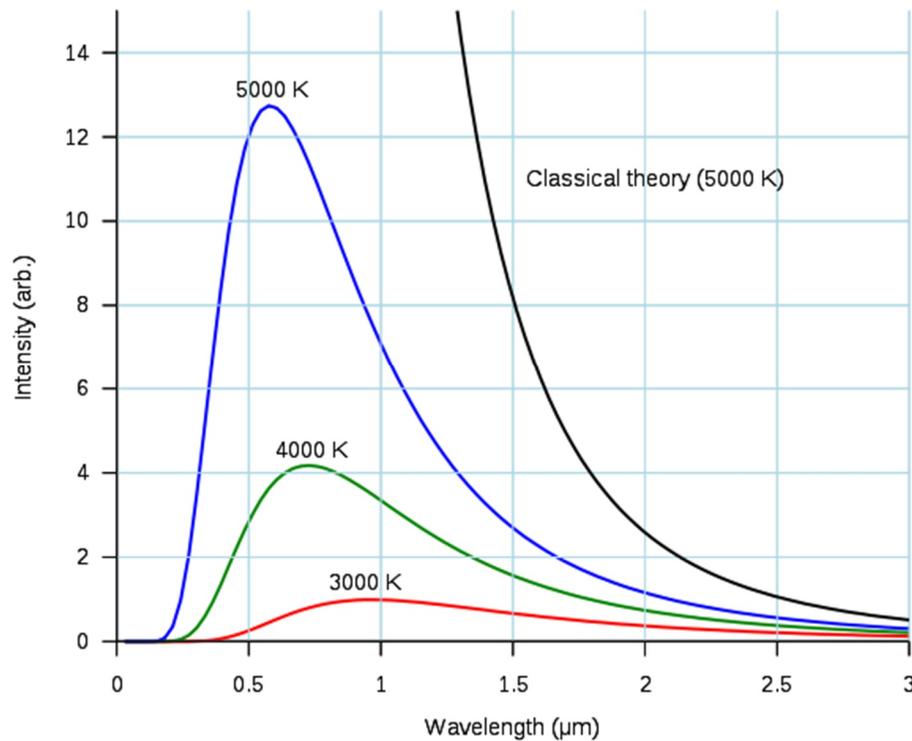

- ▶ For emissive objects or displays

colour = perception(emission)

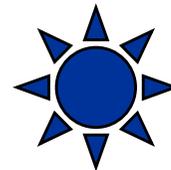

Black body radiation

- ▶ Electromagnetic radiation emitted by a perfect absorber at a given temperature
 - ▶ Graphite is a good approximation of a black body

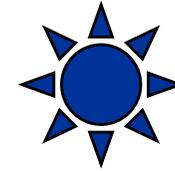

Correlated colour temperature

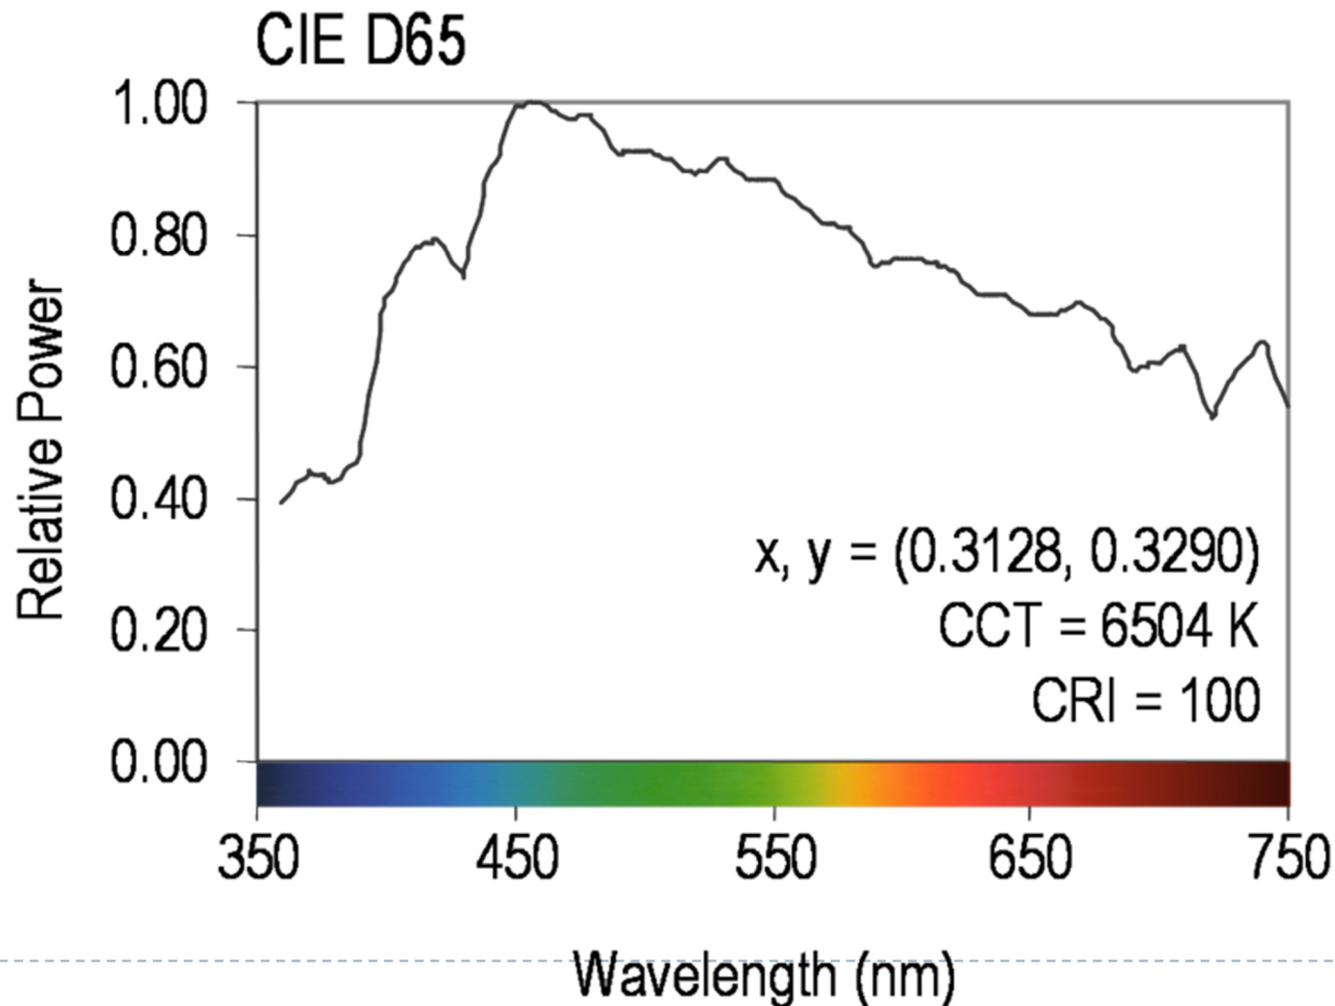

- ▶ The temperature of a black body radiator that produces light most closely matching the particular source
- ▶ **Examples:**
 - ▶ Typical north-sky light: 7500 K
 - ▶ Typical average daylight: 6500 K
 - ▶ Domestic tungsten lamp (100 to 200 W): 2800 K
 - ▶ Domestic tungsten lamp (40 to 60 W): 2700 K
 - ▶ Sunlight at sunset: 2000 K
- ▶ Useful to describe colour of the **illumination** (source of light)

Standard illuminant D65

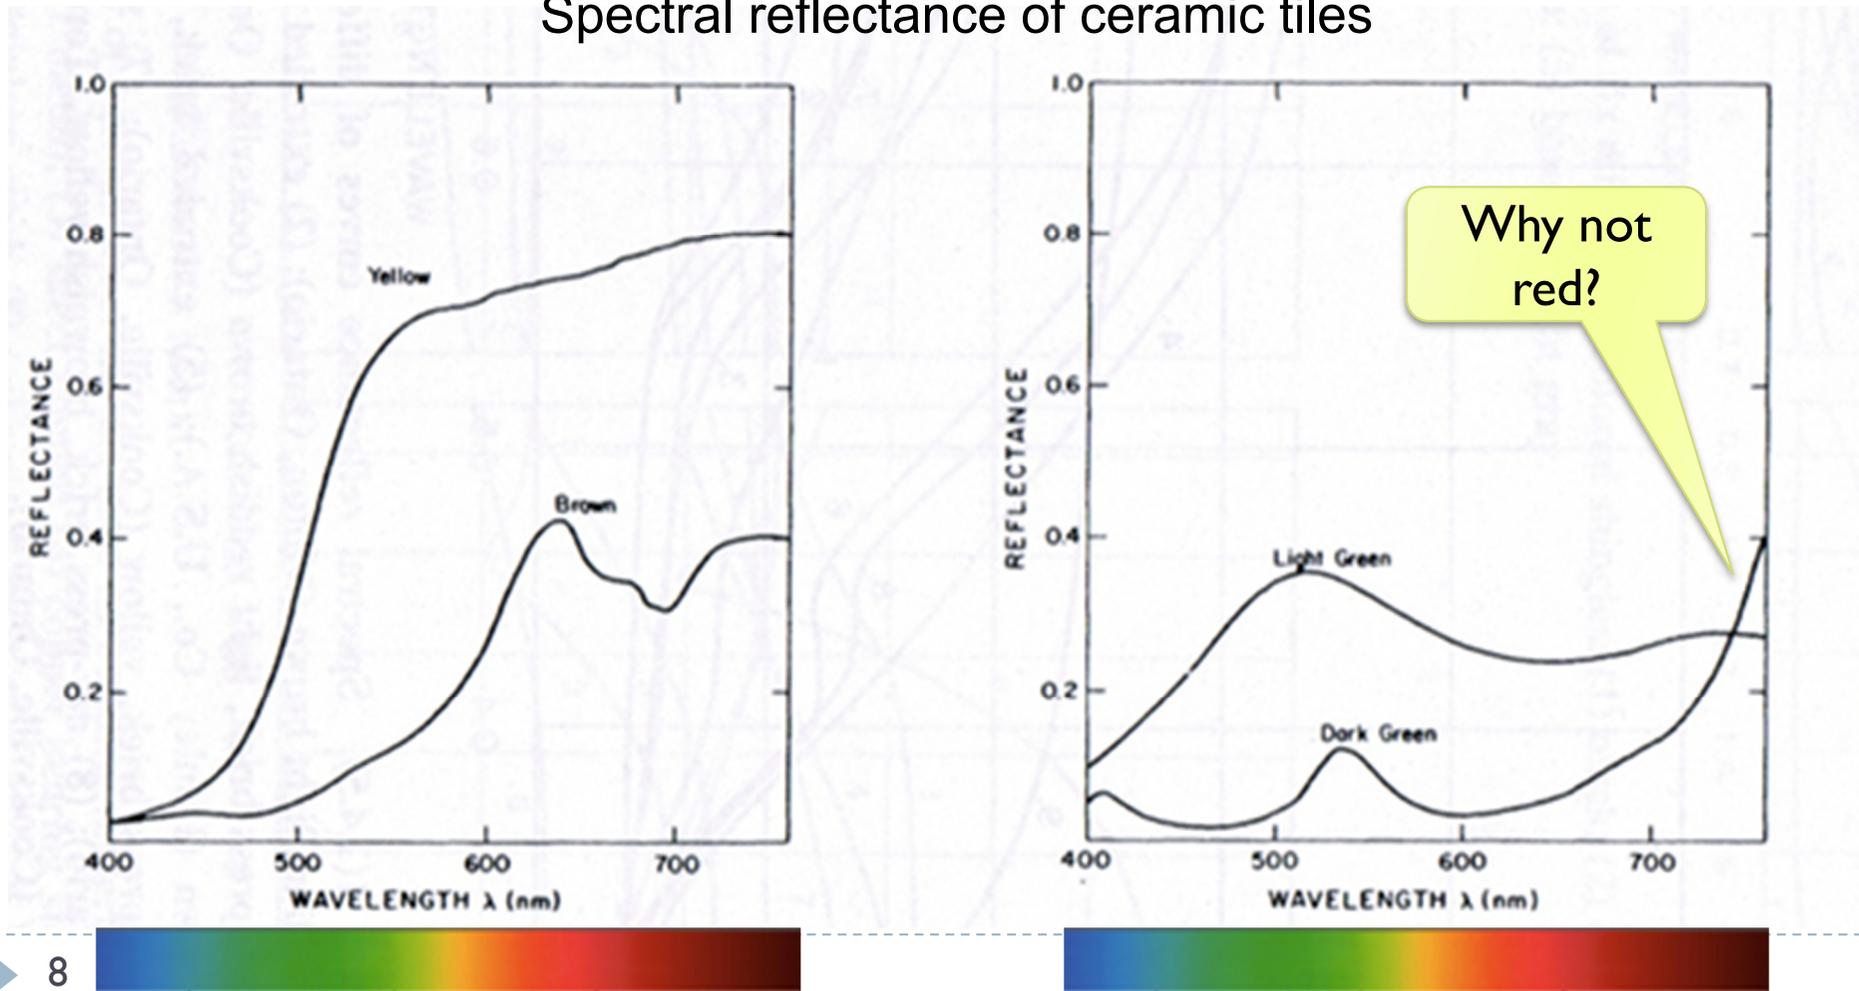

- ▶ Mid-day sun in Western Europe / Northern Europe
- ▶ Colour temperature approx. 6500 K

Reflectance

- ▶ Most of the light we see is reflected from objects
- ▶ These objects absorb a certain part of the light spectrum

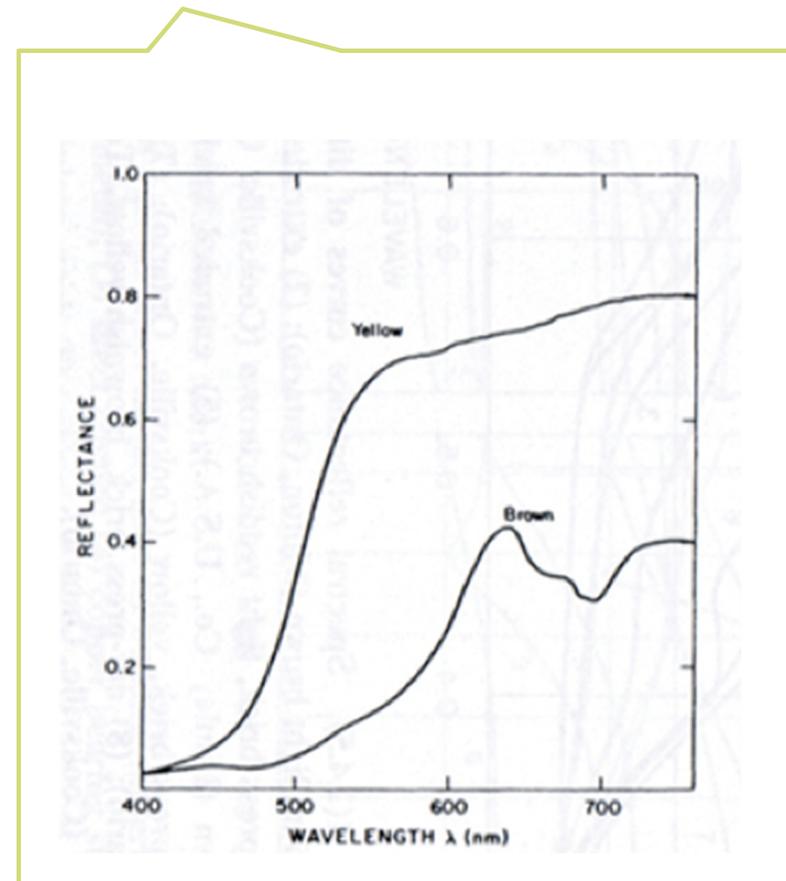

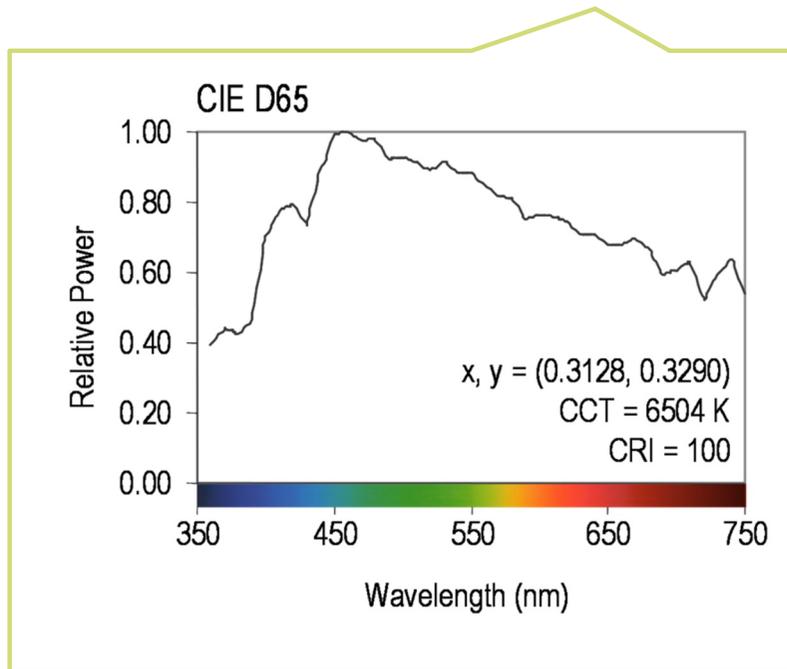

Spectral reflectance of ceramic tiles

Reflected light

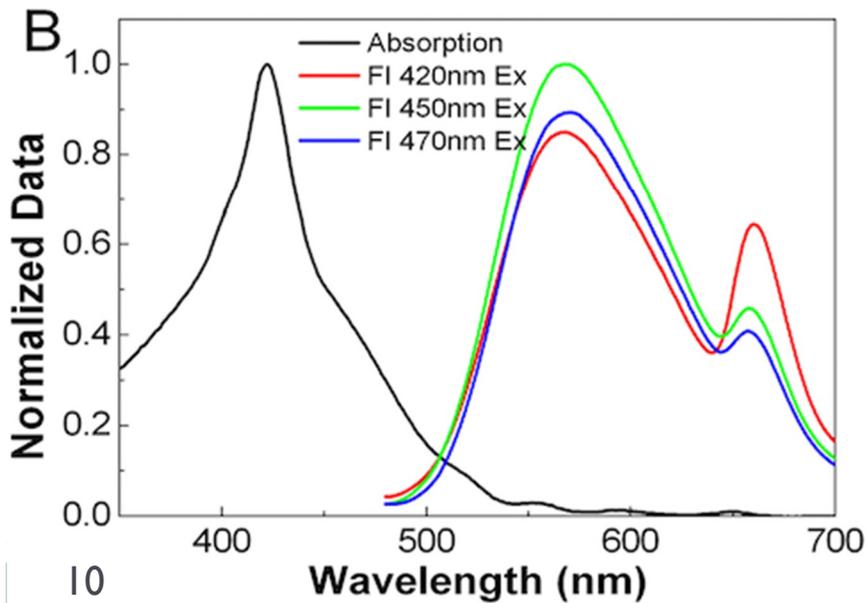

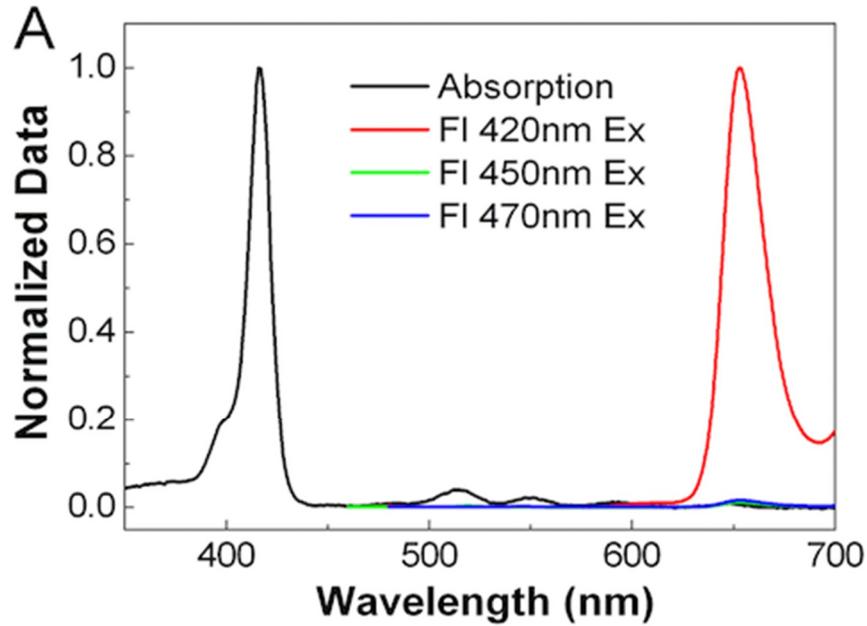

$$L(\lambda) = I(\lambda)R(\lambda)$$

- ▶ Reflected light = illumination \times reflectance

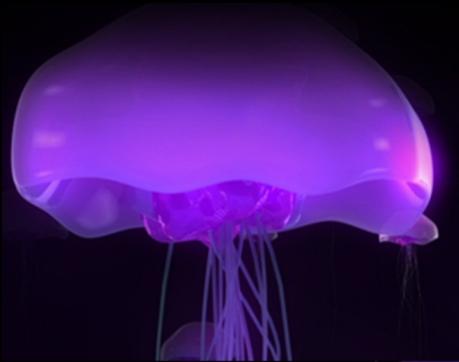

The same object may appear to have different color under different illumination.

Fluorescence

From: <http://en.wikipedia.org/wiki/Fluorescence>

Colour perception and colour spaces

Part 2/5 – perception, cone fundamentals

Rafał Mantiuk

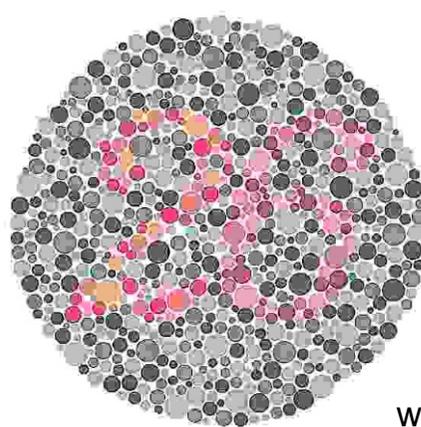

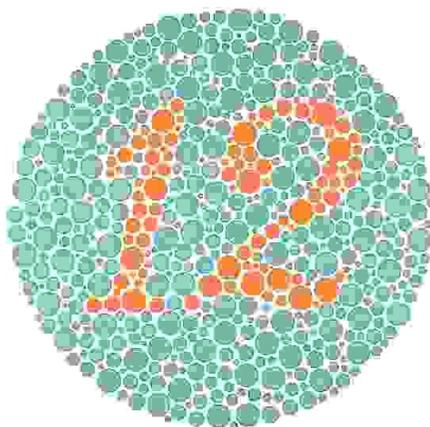

Computer Laboratory, University of Cambridge

Colour perception

- ▶ **Di-chromaticity (dogs, cats)**
 - ▶ Yellow & blue-violet
 - ▶ Green, orange, red indistinguishable
- ▶ **Tri-chromaticity (humans, monkeys)**
 - ▶ Red-ish, green-ish, blue-ish
 - ▶ Colour-deficiency
 - ▶ Most often men, green-red colour-deficiency

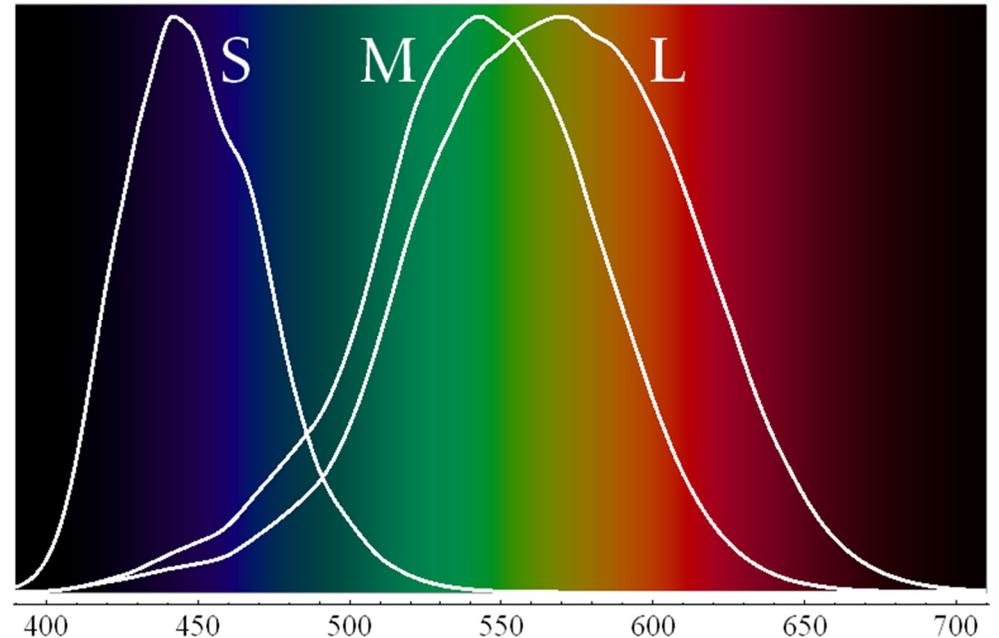

www.lam.mus.ca.us/cats/color/

www.colorcube.com/illusions/clrbld.html

Colour vision

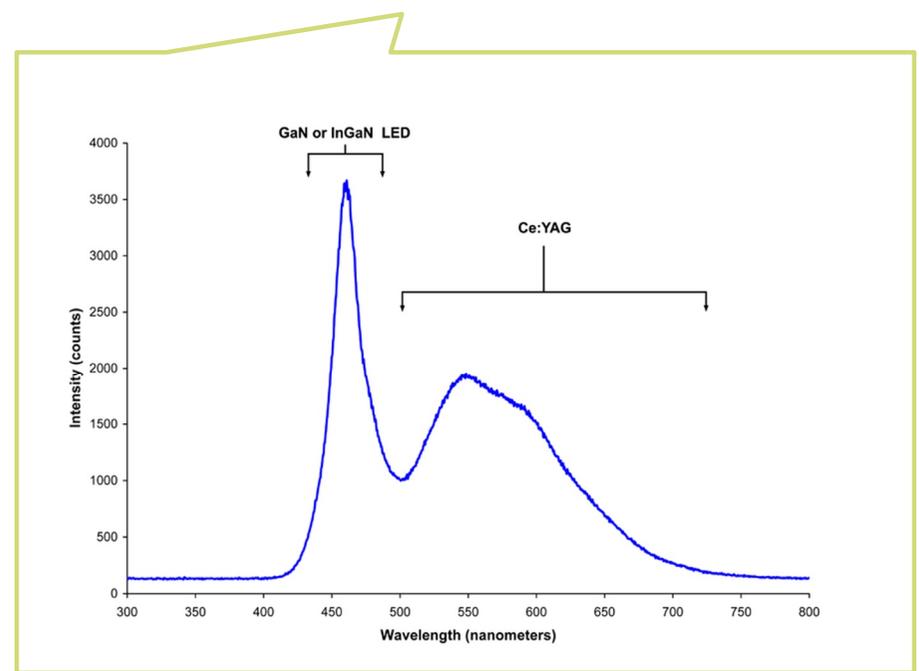

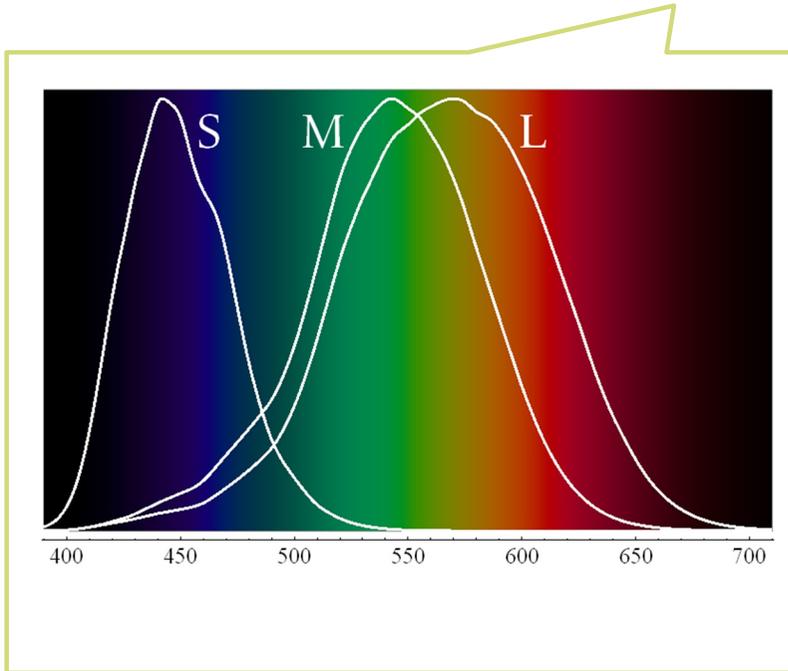

- ▶ Cones are the photoreceptors responsible for colour vision
 - ▶ Only daylight, we see no colours when there is not enough light
- ▶ Three types of cones
 - ▶ S – sensitive to short wavelengths
 - ▶ M – sensitive to medium wavelengths
 - ▶ L – sensitive to long wavelengths

Sensitivity curves – probability that a photon of that wavelength will be absorbed by a photoreceptor. S, M and L curves are normalized in this plot.

Perceived light

- ▶ cone response = sum(sensitivity × reflected light)

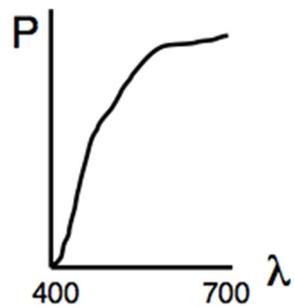

Although there is an infinite number of wavelengths, we have only three photoreceptor types to sense differences between light spectra

Formally

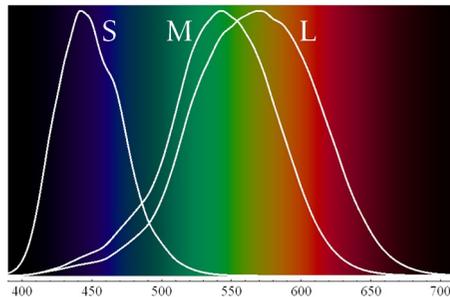

$$R_S = \int_{380}^{730} S_S(\lambda) \cdot L(\lambda) d\lambda$$

Metamers

- ▶ Even if two light spectra are different, they may appear to have the same colour
- ▶ The light spectra that appear to have the same colour are called **metamers**
- ▶ Example:

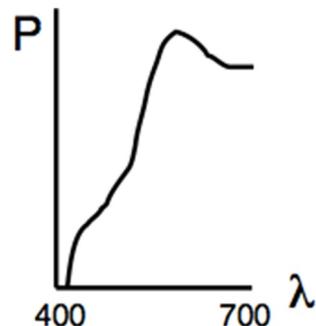

*

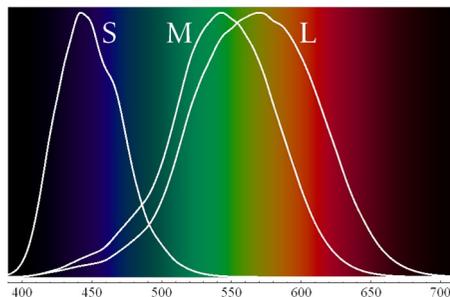

$$= [L_1, M_1, S_1]$$

||

*

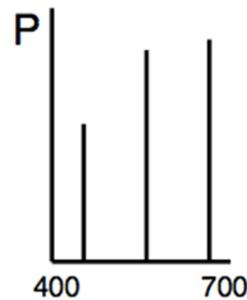

$$= [L_2, M_2, S_2]$$

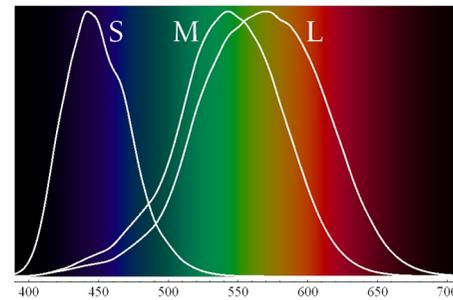

Practical application of metamerism

- ▶ Displays do not emit the same light spectra as real-world objects
- ▶ Yet, the colours on a display look almost identical

On the display

*

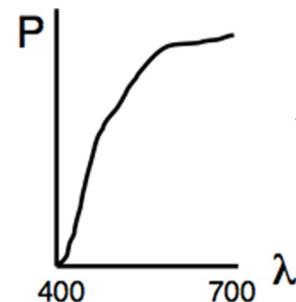

$$= [L_1, M_1, S_1]$$

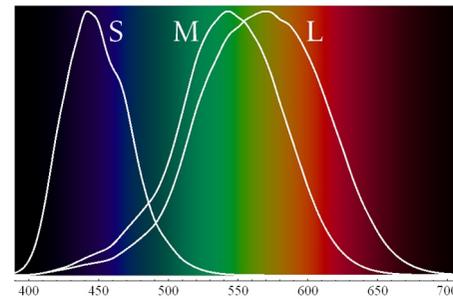

||

In real world

*

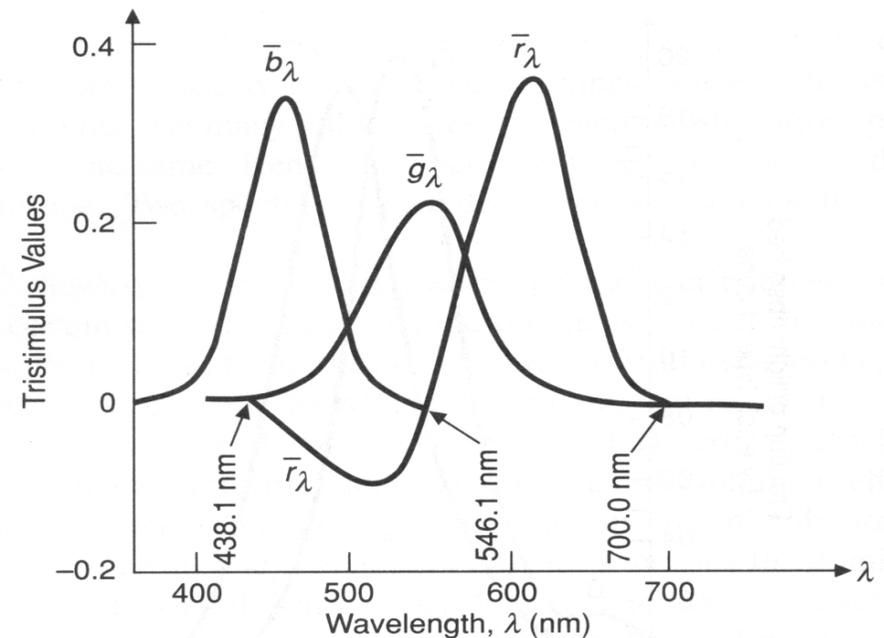

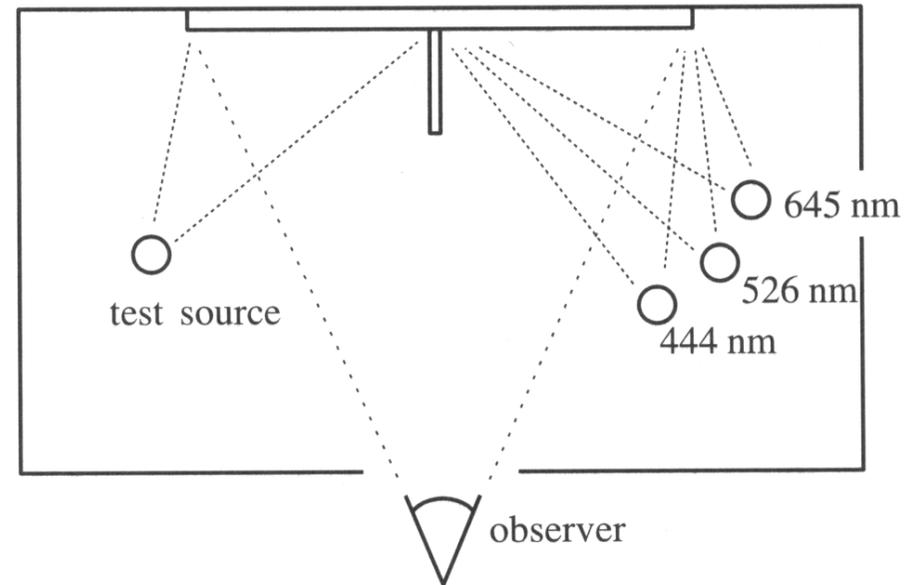

$$= [L_2, M_2, S_2]$$

Tristimulus Colour Representation

▶ Observation

- ▶ Any colour can be matched using three linear independent reference colours
- ▶ May require “negative” contribution to test colour
- ▶ Matching curves describe the value for matching monochromatic spectral colours of equal intensity
 - ▶ With respect to a certain set of primary colours

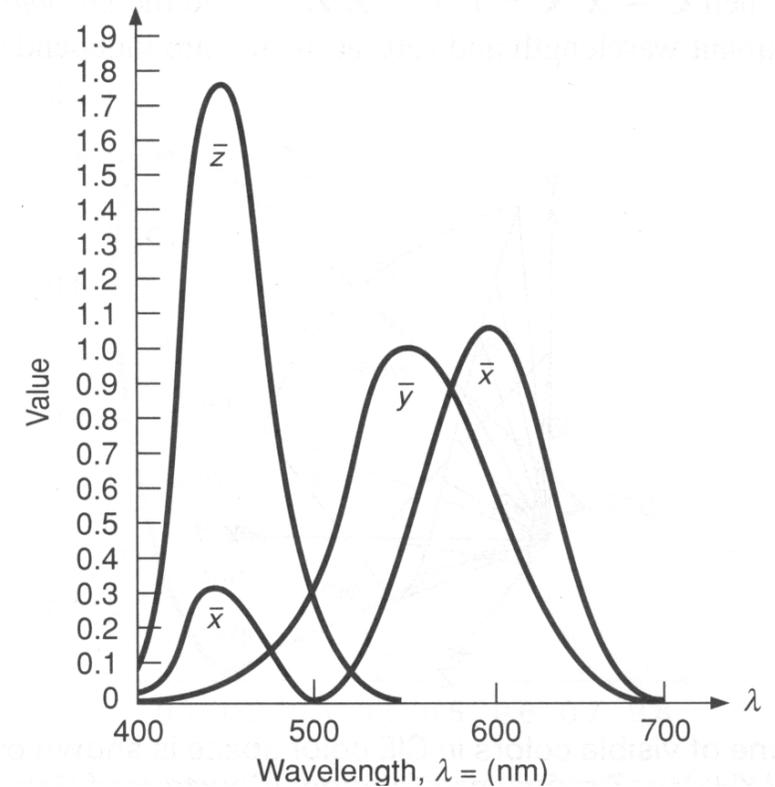

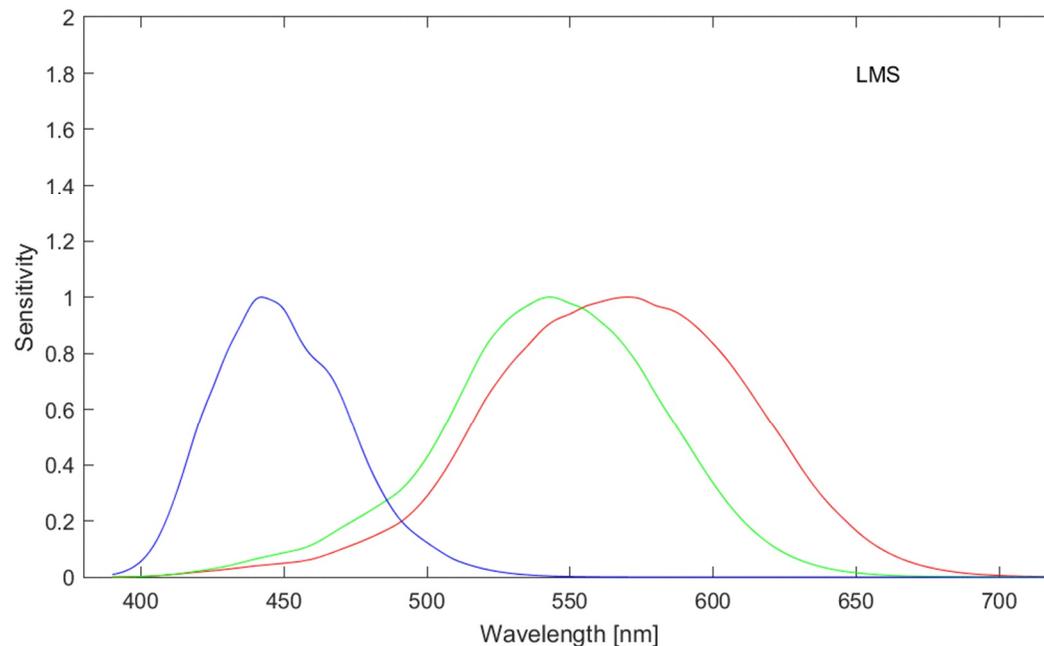

Standard Colour Space CIE-XYZ

- ▶ **CIE Experiments [Guild and Wright, 1931]**
 - ▶ Colour matching experiments
 - ▶ Group ~12 people with „normal“ colour vision
 - ▶ 2 degree visual field (fovea only)
- ▶ **CIE 2006 XYZ**
 - ▶ Derived from LMS colour matching functions by Stockman & Sharpe
 - ▶ S-cone response differs the most from CIE 1931
- ▶ **CIE-XYZ Colour Space**
 - ▶ Goals
 - ▶ Abstract from concrete primaries used in an experiment
 - ▶ All matching functions are positive
 - ▶ Primary „Y“ is roughly proportionally to achromatic response (luminance)

Standard Colour Space CIE-XYZ

▶ Standardized imaginary primaries CIE XYZ (1931)

- ▶ Could match all physically realizable colour stimuli
- ▶ Cone sensitivity curves can be obtained by a linear transformation of CIE XYZ

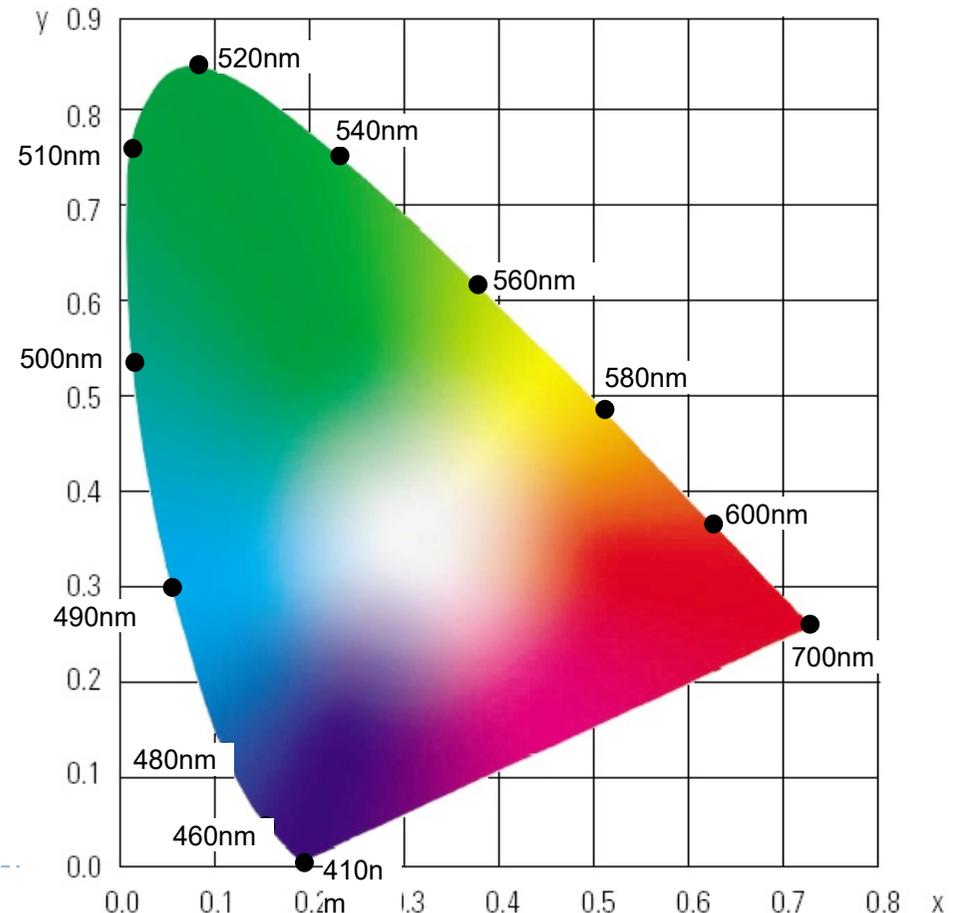

CIE chromaticity diagram

- ▶ *chromaticity* values are defined in terms of x, y, z

$$x = \frac{X}{X + Y + Z}, \quad y = \frac{Y}{X + Y + Z}, \quad z = \frac{Z}{X + Y + Z} \quad x + y + z = 1$$

- ▶ ignores luminance
- ▶ can be plotted as a 2D function
- ▶ pure colours (single wavelength) lie along the outer curve
- ▶ all other colours are a mix of pure colours and hence lie inside the curve
- ▶ points outside the curve do not exist as colours

Colour perception and colour spaces

Part 4/5 – gamuts, linear and gamma-encoded colour

Rafał Mantiuk

Computer Laboratory, University of Cambridge

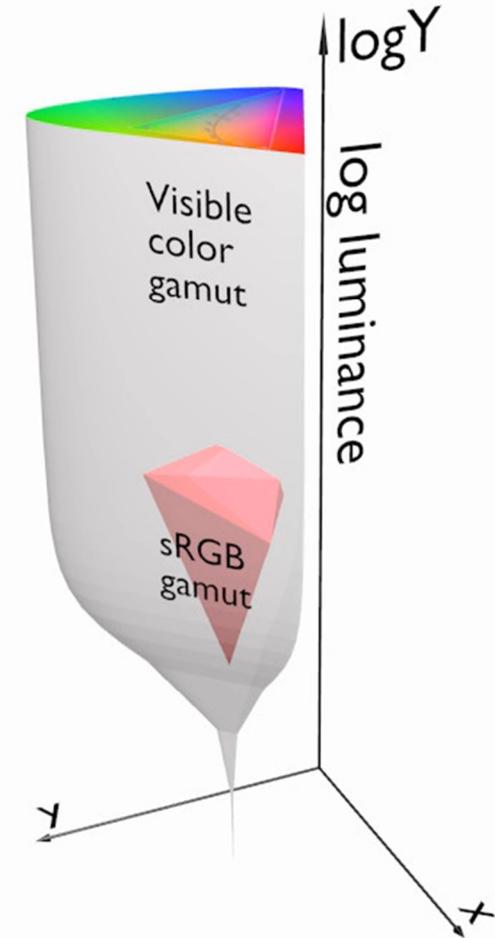

Visible vs. displayable colours

- ▶ All physically possible and visible colours form a solid in the XYZ space
- ▶ Each display device can reproduce a subspace of that space
- ▶ A chromacity diagram is a projection of a slice taken from a 3D solid in XYZ space
- ▶ Colour Gamut – the solid in a colour space
 - ▶ Usually defined in XYZ to be device-independent

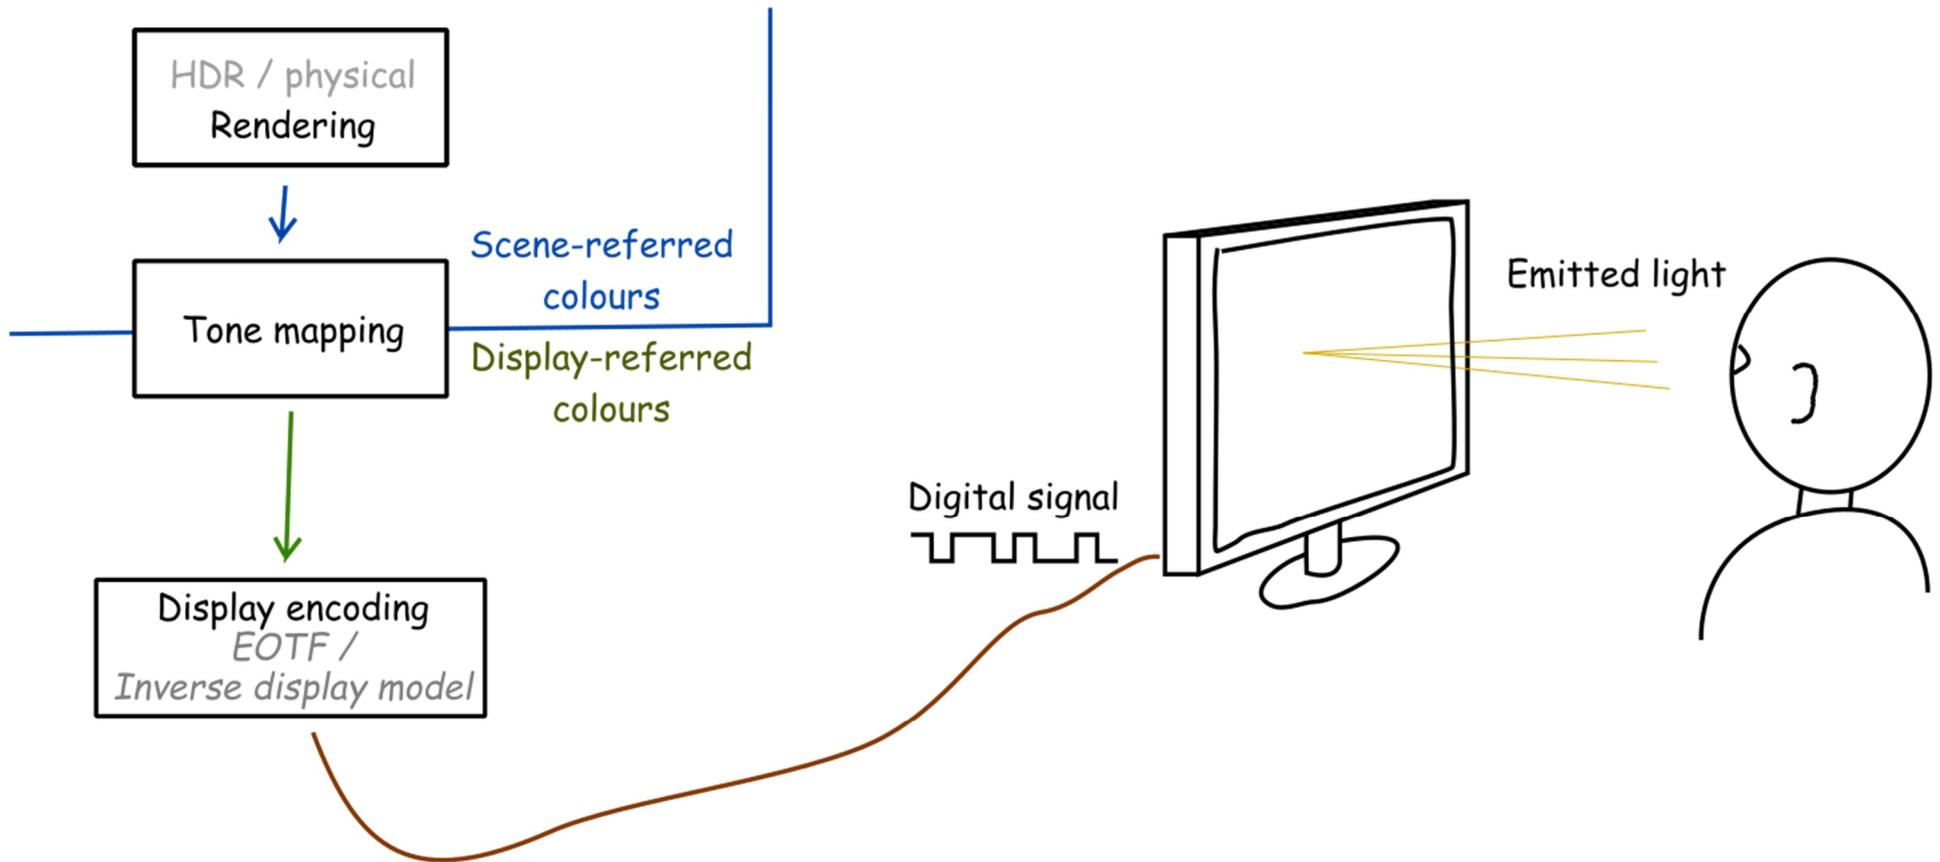

Standard vs. High Dynamic Range

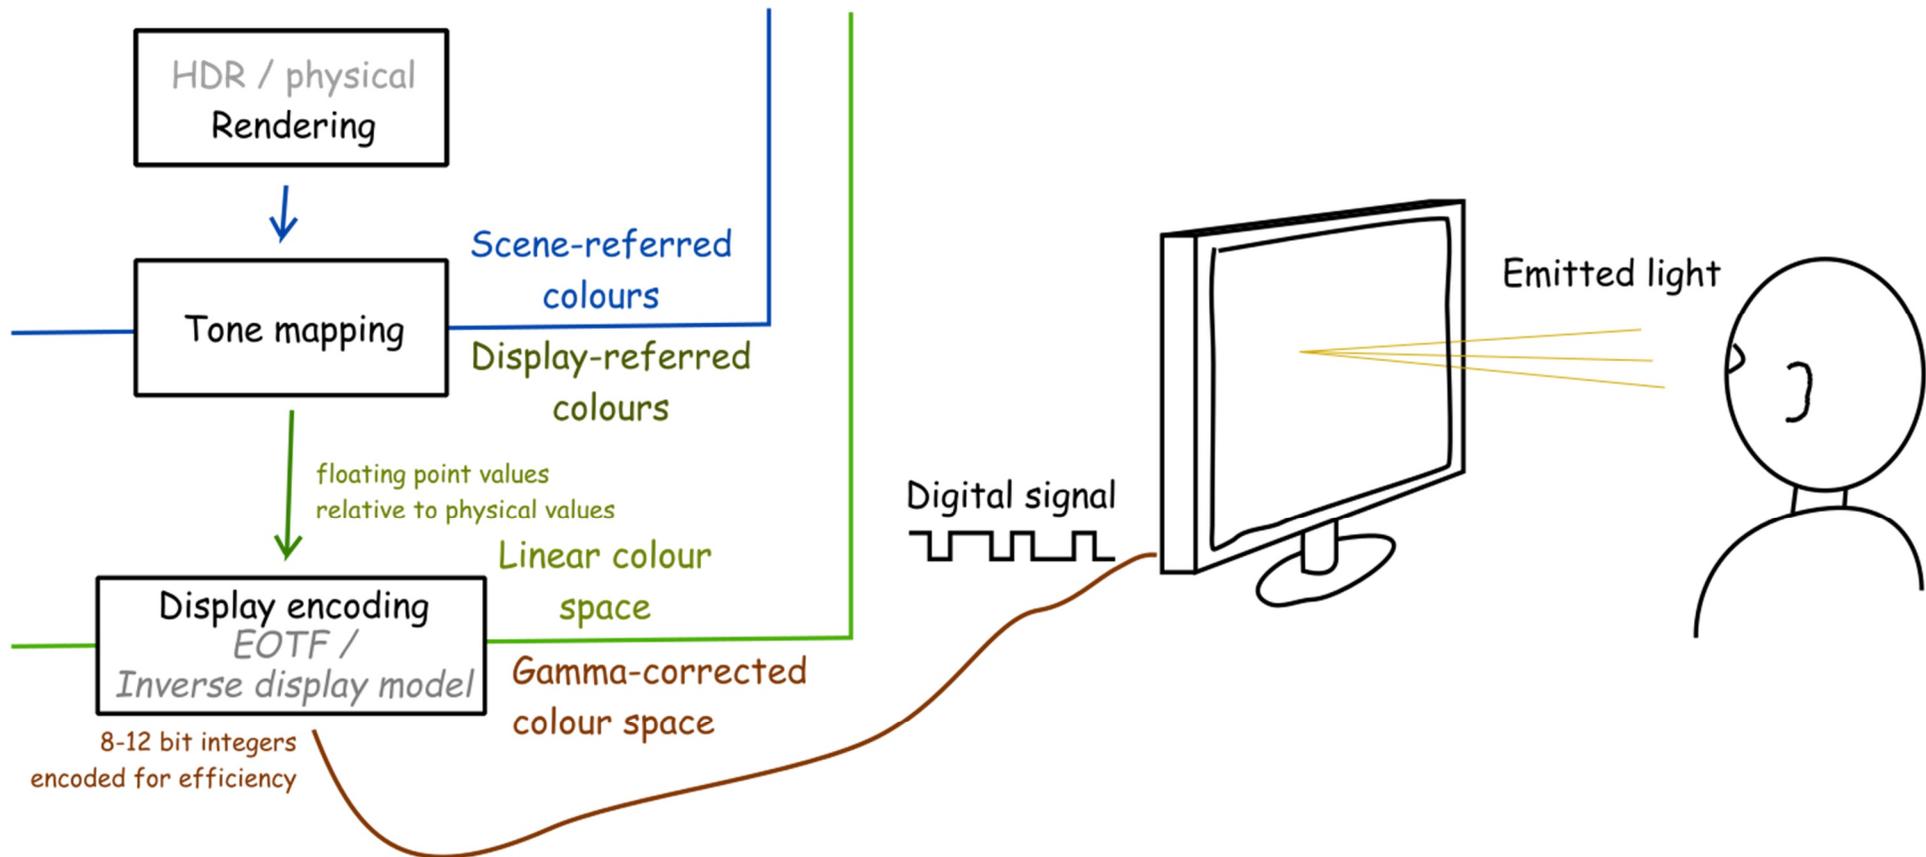

- ▶ **HDR** cameras/formats/displays attempt capture/represent/reproduce (almost) all visible colours
 - ▶ They represent scene colours and therefore we often call this representation *scene-referred*
- ▶ **SDR** cameras/formats/devices attempt to capture/represent/reproduce only colours of a standard sRGB colour gamut, mimicking the capabilities of CRTs monitors
 - ▶ They represent display colours and therefore we often call this representation *display-referred*

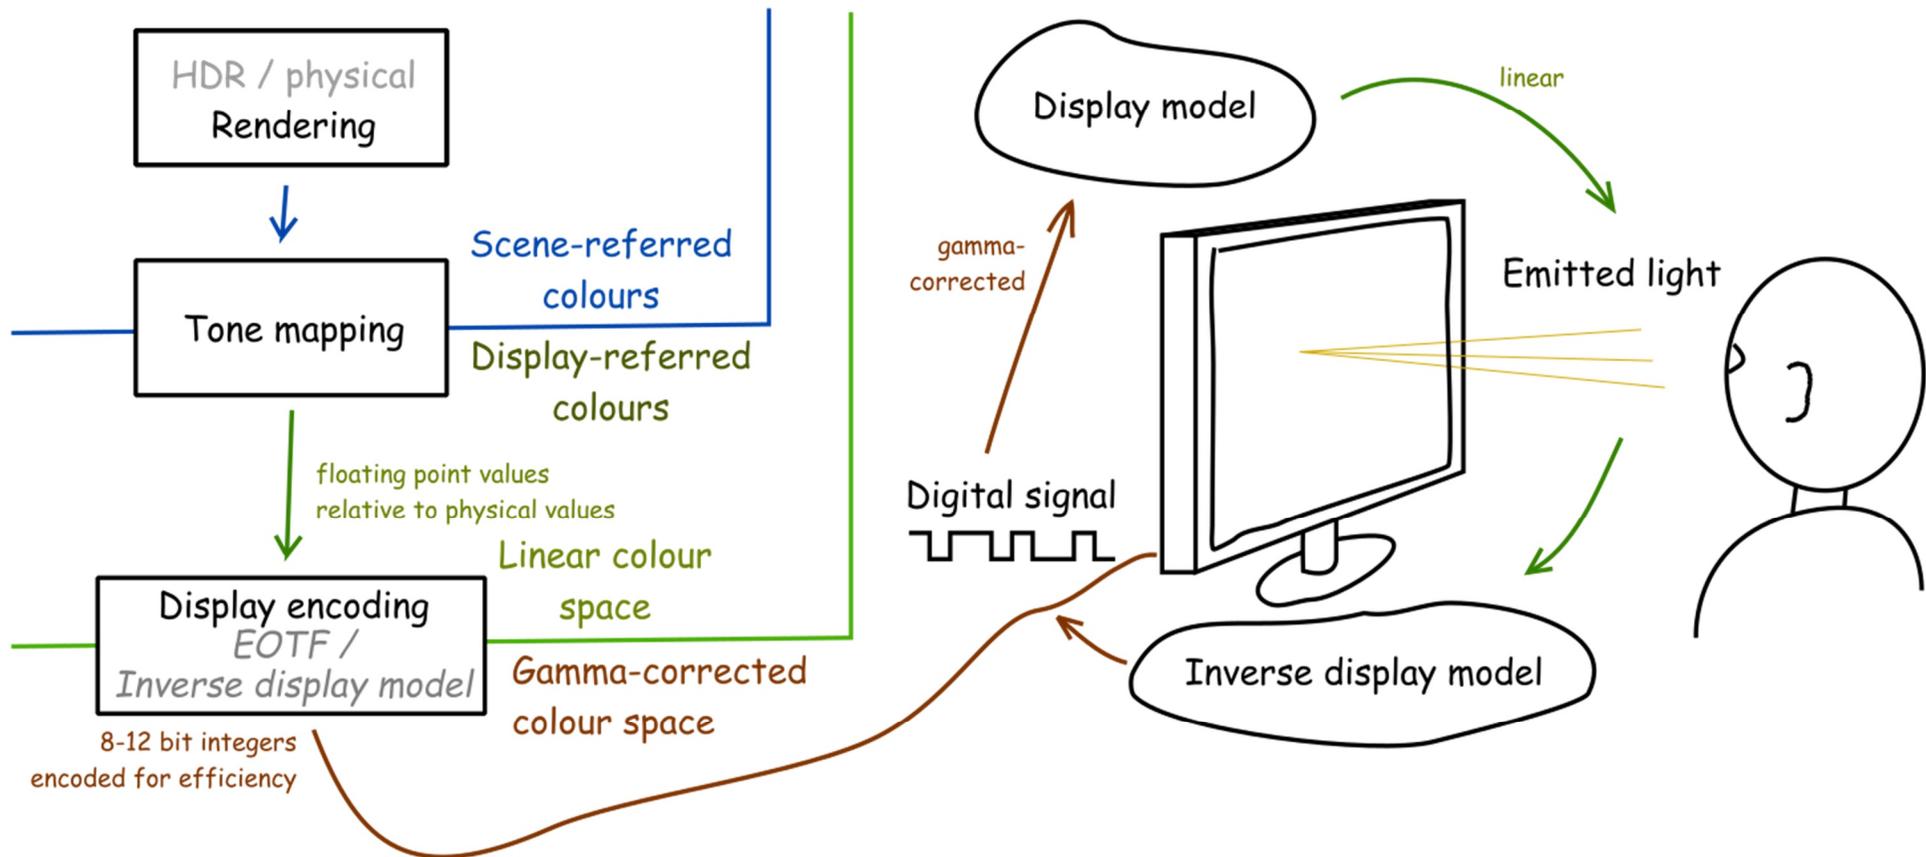

From rendering to display

From rendering to display

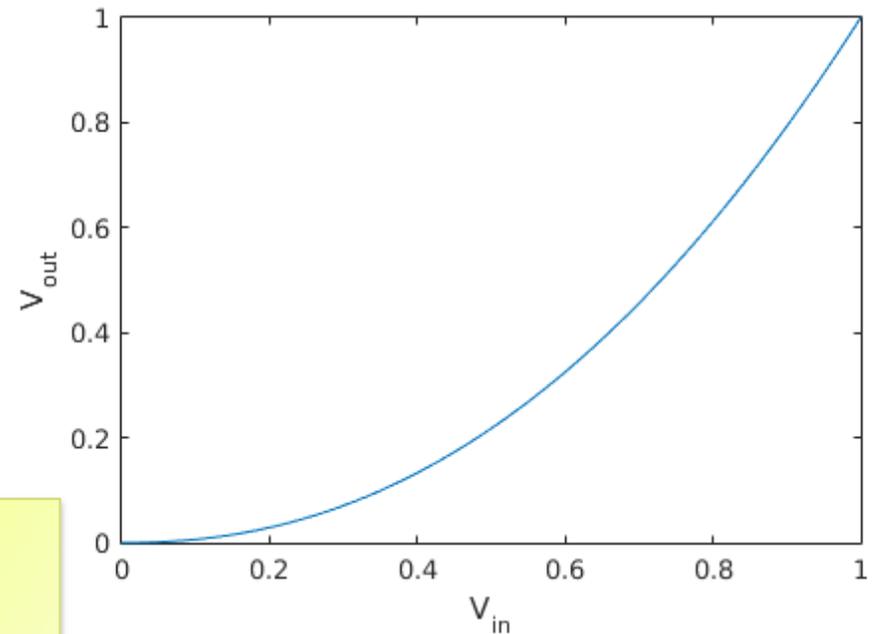

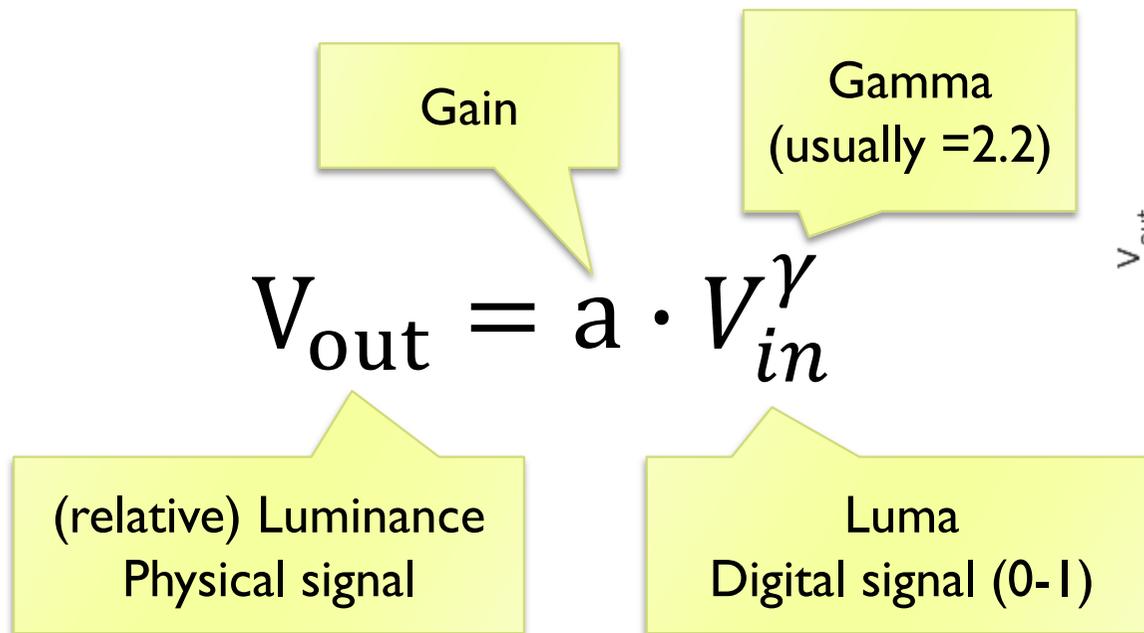

From rendering to display

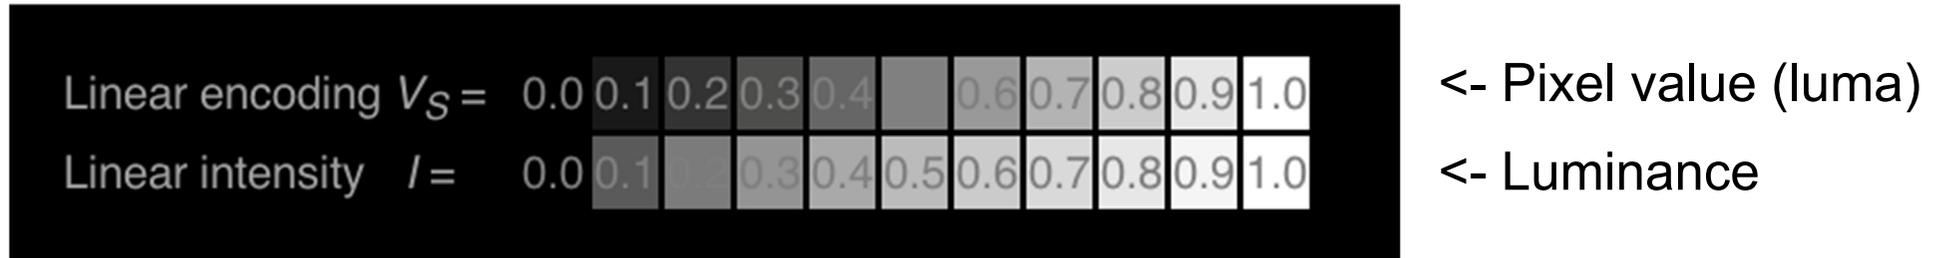

Display encoding for SDR: gamma

- ▶ Gamma correction is often used to encode luminance or tristimulus color values (RGB) in imaging systems (displays, printers, cameras, etc.)

Colour: the same equation applied to red, green and blue colour channels.

Why is gamma needed?

- ▶ *Gamma-corrected* pixel values give a scale of brightness levels that is more perceptually uniform
- ▶ At least 12 bits (instead of 8) would be needed to encode each color channel without gamma correction
- ▶ And accidentally it was also the response of the CRT gun

Luma – gray-scale pixel value

- ▶ **Luma** - pixel “brightness” in *gamma corrected* units

$$L' = 0.2126R' + 0.7152G' + 0.0722B'$$

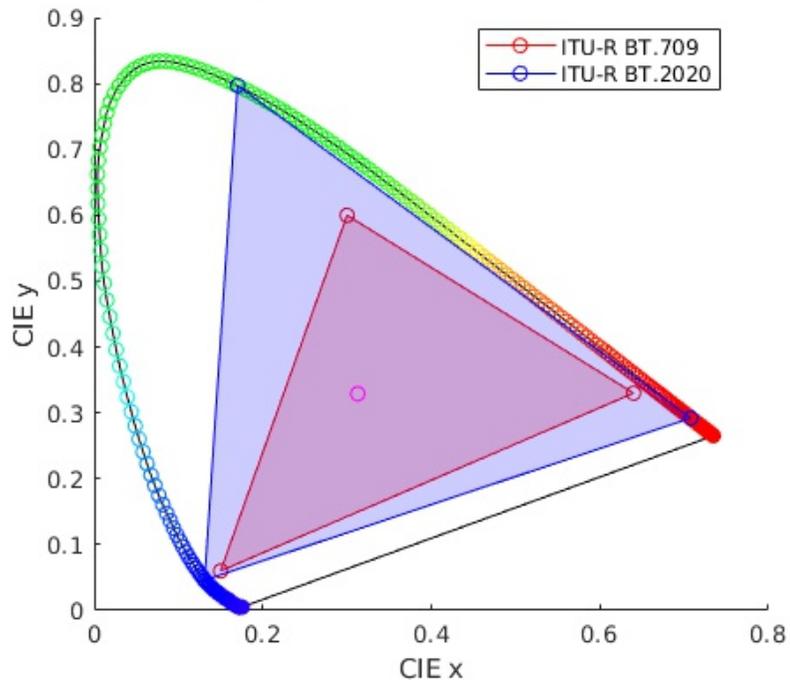

- ▶ R' , G' and B' are *gamma-corrected* colour values
 - ▶ Prime symbol denotes *gamma corrected*
 - ▶ Used in image/video coding
-
- ▶ Note that relative **luminance** is often approximated with
$$L = 0.2126R + 0.7152G + 0.0722B$$
$$= 0.2126(R')^\gamma + 0.7152(G')^\gamma + 0.0722(B')^\gamma$$
 - ▶ R , G , and B are *linear* colour values
 - ▶ Luma and luminance are different quantities despite similar formulas

Standards for display encoding

Display type	Colour space	EOTF	Bit depth
Standard Dynamic Range	ITU-R 709	2.2 gamma / sRGB	8 to 10
High Dynamic Range	ITU-R 2020	ITU-R 2100 (PQ/HLG)	10 to 12

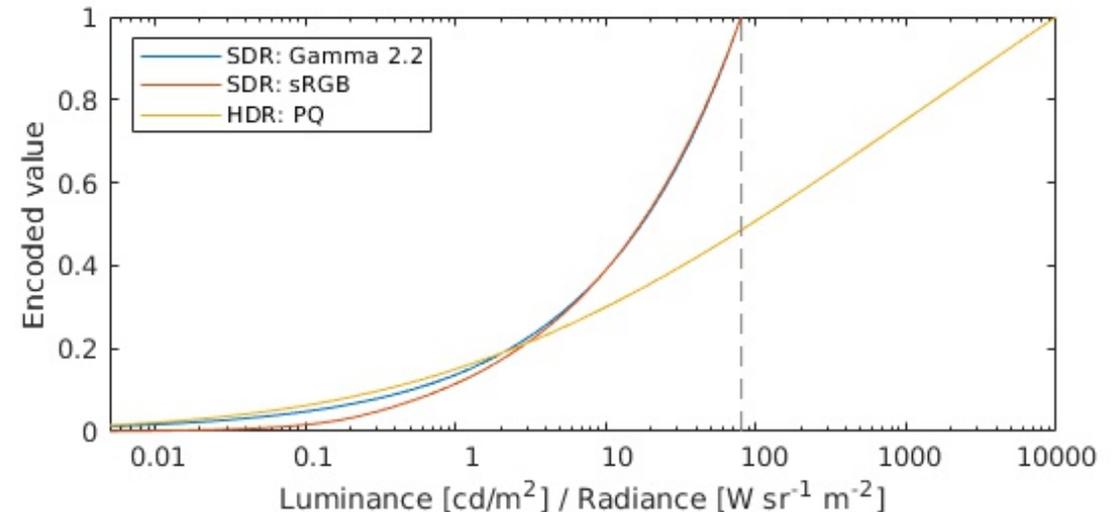

Colour space

What is the XYZ of “pure” red, green and blue

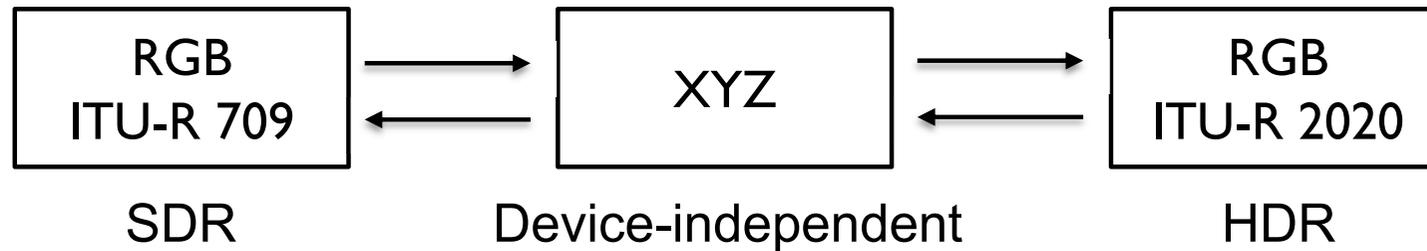

Electro-Optical Transfer Function

How to efficiently encode each primary colour

How to transform between linear RGB colour spaces?

► From ITU-R 709 RGB to XYZ:

$$\begin{bmatrix} X \\ Y \\ Z \end{bmatrix} = \begin{bmatrix} 0.4124 & 0.3576 & 0.1805 \\ 0.2126 & 0.7152 & 0.0722 \\ 0.0193 & 0.1192 & 0.9505 \end{bmatrix}_{R709toXYZ} \cdot \begin{bmatrix} R \\ G \\ B \end{bmatrix}_{R709}$$

Relative XYZ
of the red
primary

Relative XYZ
of the green
primary

Relative XYZ
of the blue
primary

Relative RGB
(0-1) in the
R709 space

How to transform between RGB colour spaces?

- ▶ From ITU-R **709** RGB to ITU-R **2020** RGB:

$$\begin{bmatrix} R \\ G \\ B \end{bmatrix}_{R2020} = M_{XYZtoR2020} \cdot M_{R709toXYZ} \cdot \begin{bmatrix} R \\ G \\ B \end{bmatrix}_{R709}$$

- ▶ From ITU-R **2020** RGB to ITU-R **709** RGB:

$$\begin{bmatrix} R \\ G \\ B \end{bmatrix}_{R709} = M_{XYZtoR709} \cdot M_{R2020toXYZ} \cdot \begin{bmatrix} R \\ G \\ B \end{bmatrix}_{R2020}$$

- ▶ Where:

$$M_{R709toXYZ} = \begin{bmatrix} 0.4124 & 0.3576 & 0.1805 \\ 0.2126 & 0.7152 & 0.0722 \\ 0.0193 & 0.1192 & 0.9505 \end{bmatrix} \text{ and } M_{XYZtoR709} = M_{R709toXYZ}^{-1}$$

$$M_{R2020toXYZ} = \begin{bmatrix} 0.6370 & 0.1446 & 0.1689 \\ 0.2627 & 0.6780 & 0.0593 \\ 0.0000 & 0.0281 & 1.0610 \end{bmatrix} \text{ and } M_{XYZtoR2020} = M_{R2020toXYZ}^{-1}$$

UNIVERSITY OF
CAMBRIDGE
COMPUTER LABORATORY

Advanced Graphics and Image Processing

Colour perception and colour spaces

Part 5/5 – colour spaces

Rafał Mantiuk

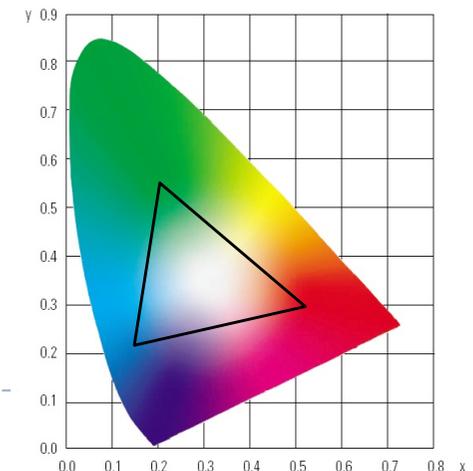

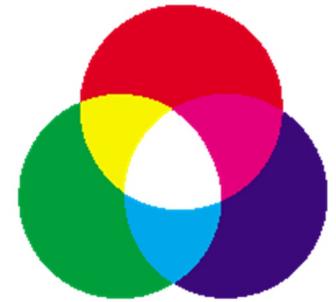

Computer Laboratory, University of Cambridge

Representing colour

- ▶ We need a way to represent colour in the computer by some set of numbers
 - ▶ A) preferably a small set of numbers which can be quantised to a fairly **small number of bits** each
 - ▶ Gamma corrected RGB, sRGB and CMYK for printers
 - ▶ B) a set of numbers that are **easy to interpret**
 - ▶ Munsell's *artists'* scheme
 - ▶ HSV, HLS
 - ▶ C) a set of numbers in a 3D space so that the (Euclidean) distance in that space corresponds to approximately **perceptually uniform** colour differences
 - ▶ CIE Lab, CIE Luv

RGB spaces

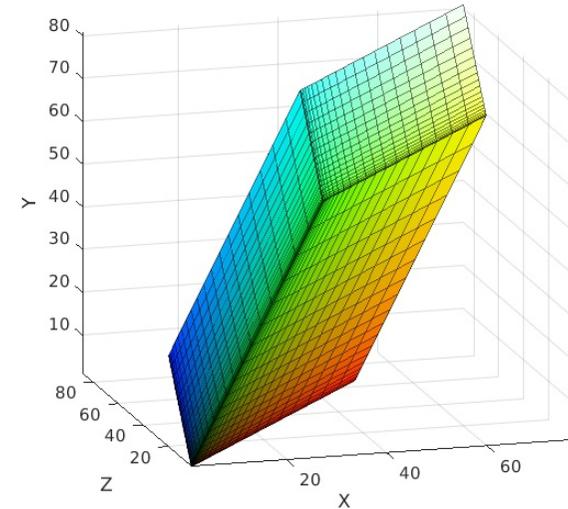

- ▶ Most display devices that output light mix red, green and blue lights to make colour
 - ▶ televisions, CRT monitors, LCD screens
- ▶ RGB colour space
 - ▶ Can be **linear** (RGB) or **display-encoded** (R'G'B')
 - ▶ Can be **scene-referred** (HDR) or **display-referred** (SDR)
- ▶ There are multiple RGB colour spaces
 - ▶ ITU-R 709 (sRGB), ITU-R 2020, Adobe RGB, DCI-P3
 - ▶ Each using different primary colours
 - ▶ And different OETFs (gamma, PQ, etc.)
- ▶ Nominally, *RGB* space is a cube

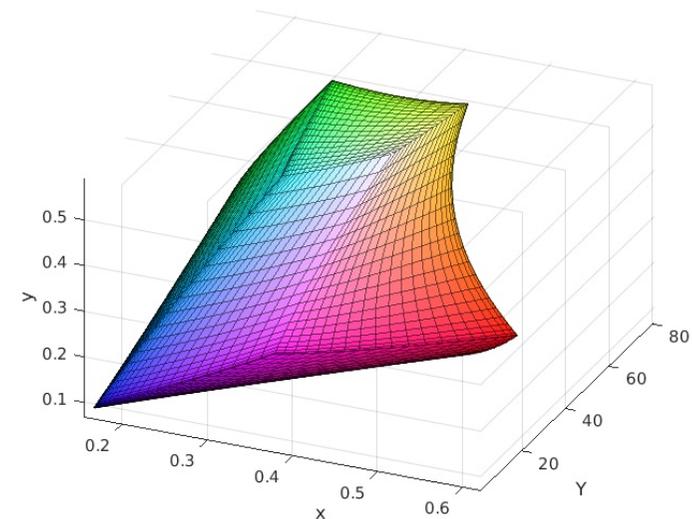

RGB in CIE XYZ space

- ▶ Linear RGB colour values can be transformed into CIE XYZ
 - ▶ by matrix multiplication
 - ▶ because it is a rigid transformation the colour gamut in CIE XYZ is a rotate and skewed cube
- ▶ Transformation into Yxy
 - ▶ is non-linear (non-rigid)
 - ▶ colour gamut is more complicated

RGB gamut in XYZ colour space

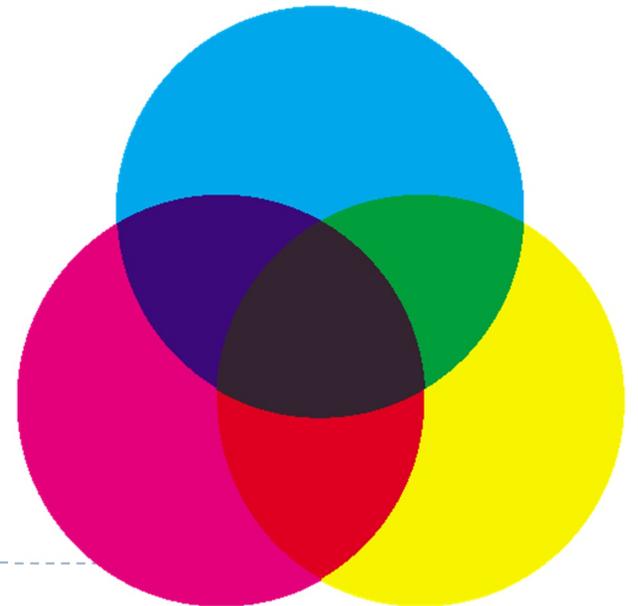

RGB gamut in Yxy colour space

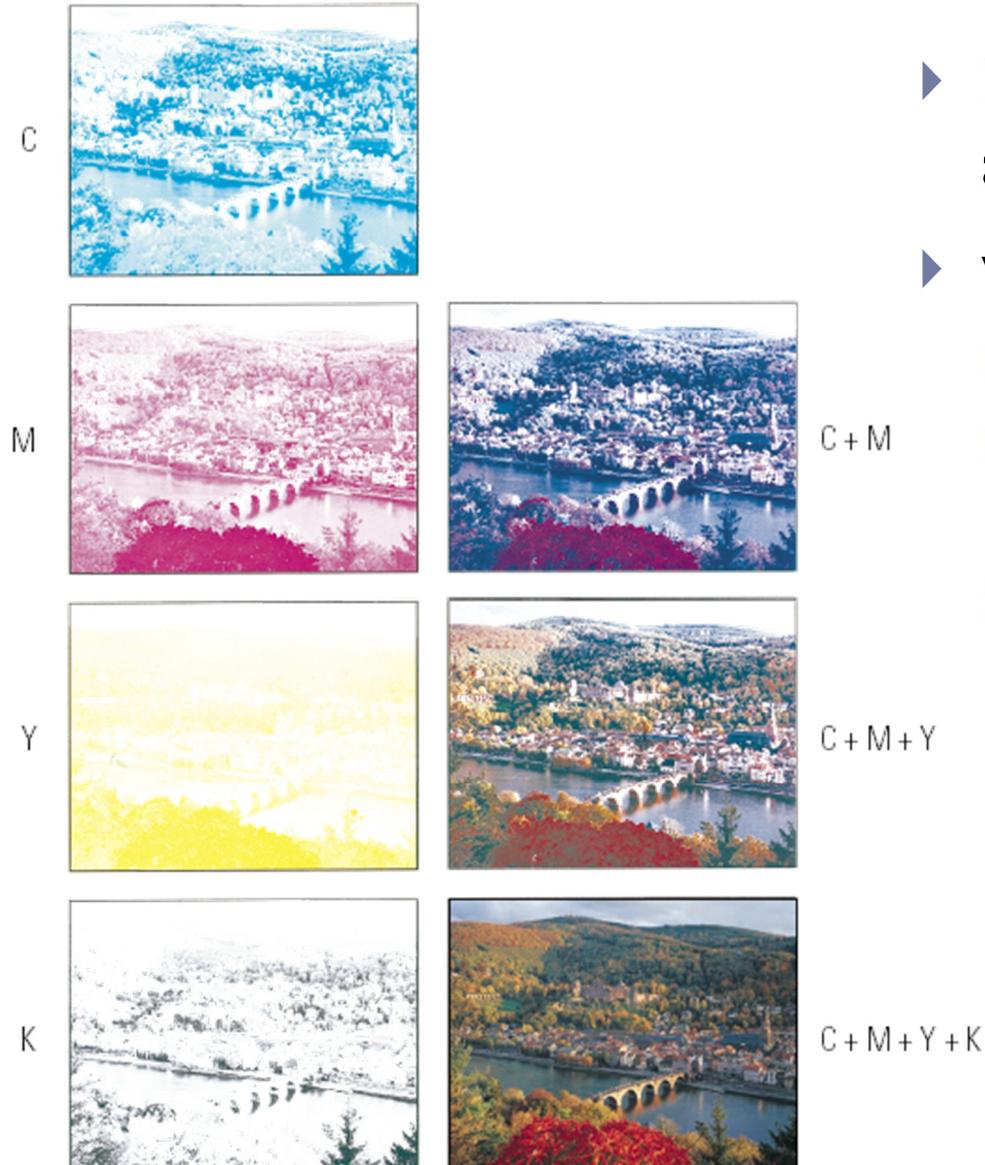

CMY space

- ▶ printers make colour by mixing coloured inks
- ▶ the important difference between inks (*CMY*) and lights (*RGB*) is that, while lights *emit* light, inks *absorb* light
 - ▶ cyan absorbs red, reflects blue and green
 - ▶ magenta absorbs green, reflects red and blue
 - ▶ yellow absorbs blue, reflects green and red
- ▶ *CMY* is, at its simplest, the inverse of *RGB*
- ▶ *CMY* space is nominally a cube

CMYK space

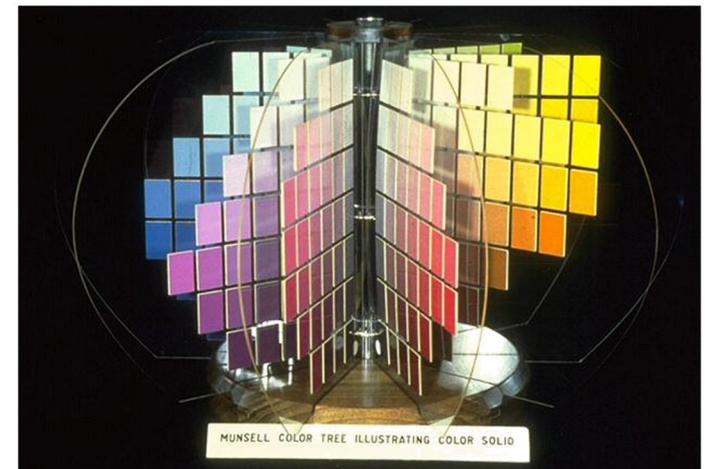

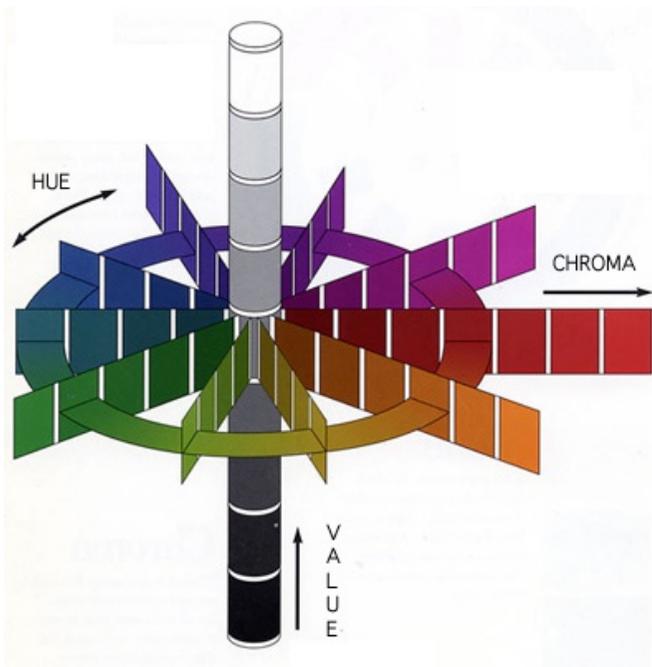

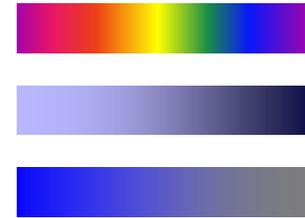

- ▶ in real printing we use black (key) as well as *CMY*
- ▶ why use black?
 - ▶ inks are not perfect absorbers
 - ▶ mixing $C + M + Y$ gives a muddy grey, not black
 - ▶ lots of text is printed in black: trying to align C, M and Y perfectly for black text would be a nightmare

Munsell's colour classification system

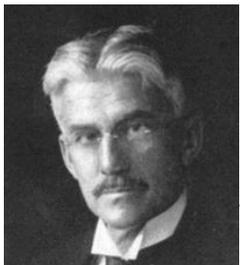

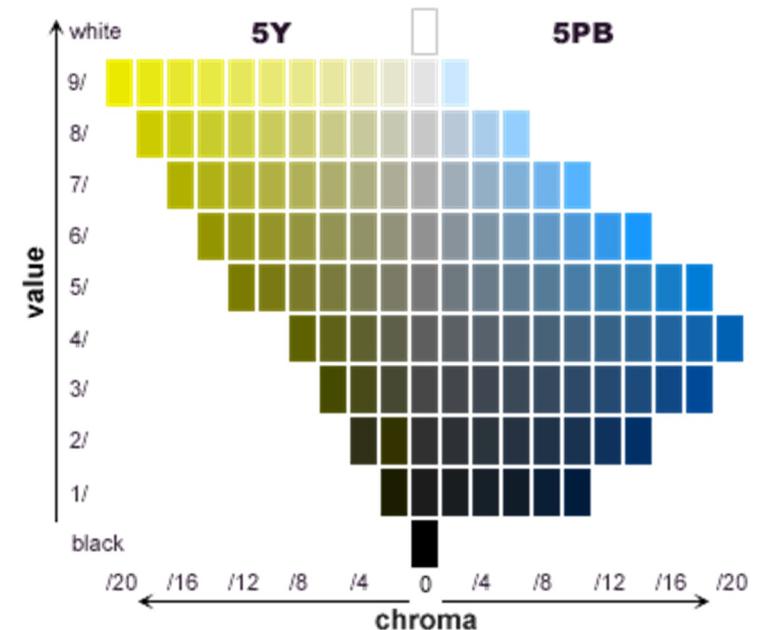

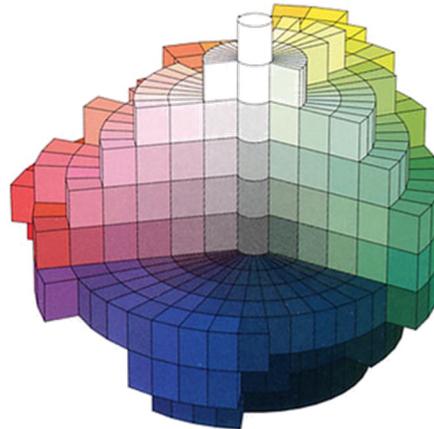

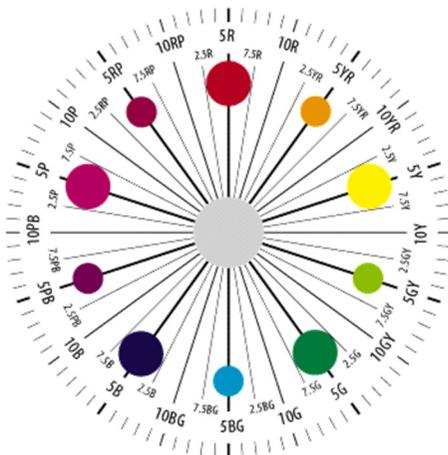

- ▶ three axes

- ▶ hue ➤ the dominant colour
 - ▶ value ➤ bright colours/dark colours
 - ▶ chroma ➤ vivid colours/dull colours
- ▶ can represent this as a 3D graph

Munsell's colour classification system

- ▶ any two adjacent colours are a standard “perceptual” distance apart
 - ▶ worked out by testing it on people
 - ▶ a highly irregular space
 - ▶ e.g. vivid yellow is much brighter than vivid blue

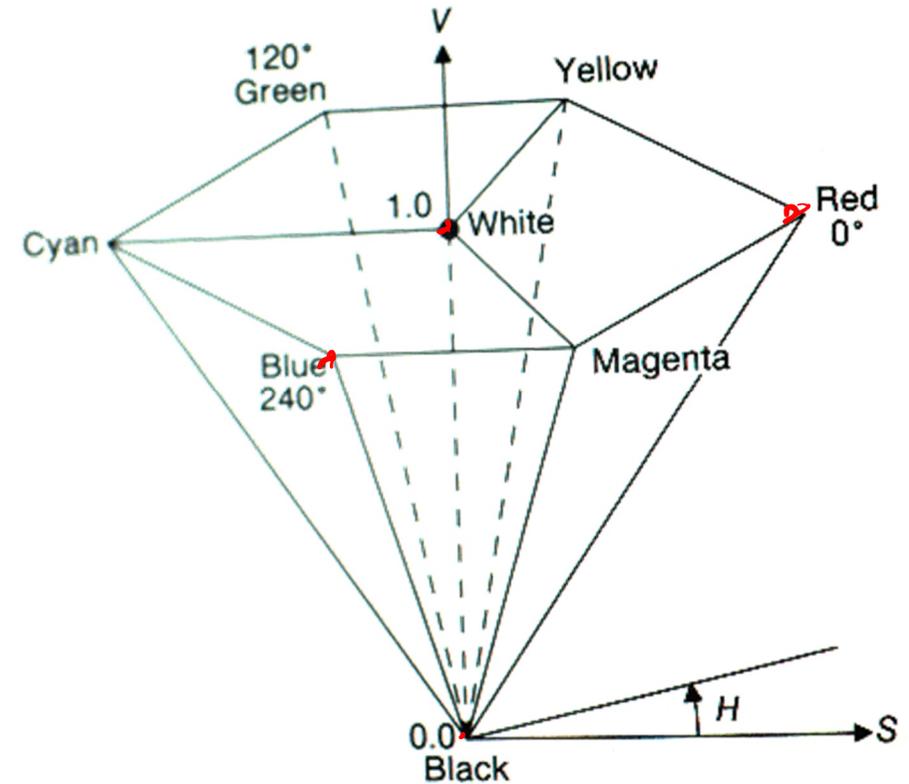

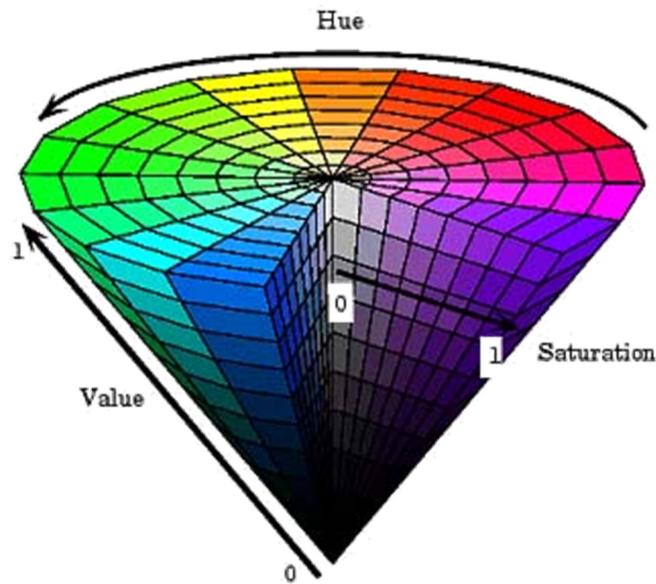

invented by Albert H. Munsell, an American artist, in 1905 in an attempt to systematically classify colours

Colour spaces for user-interfaces

- ▶ *RGB* and *CMY* are based on the physical devices which produce the coloured output
- ▶ *RGB* and *CMY* are difficult for humans to use for selecting colours
- ▶ Munsell's colour system is much more intuitive:
 - ▶ hue — what is the principal colour?
 - ▶ value — how light or dark is it?
 - ▶ chroma — how vivid or dull is it?
- ▶ computer interface designers have developed basic transformations of *RGB* which resemble Munsell's human-friendly system

HSV: hue saturation value

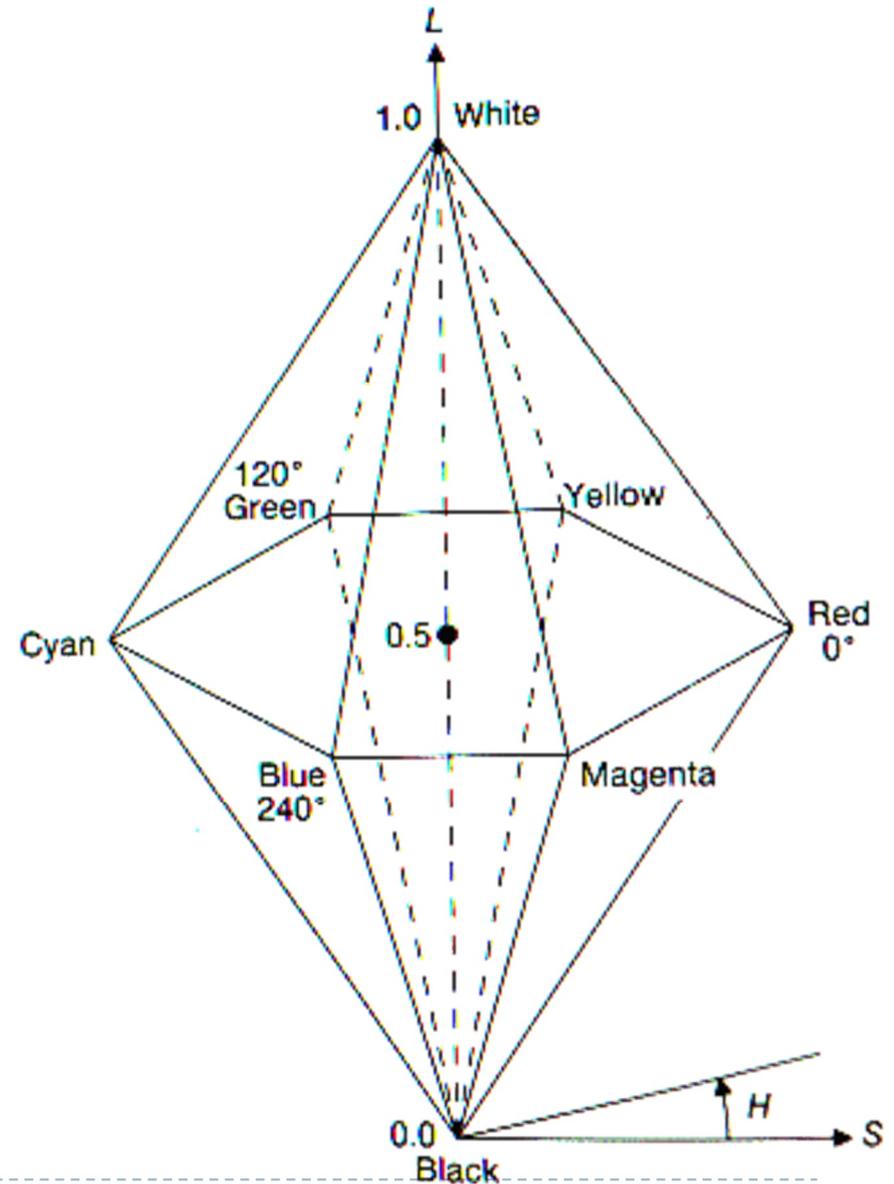

- ▶ three axes, as with Munsell
 - ▶ hue and value have same meaning
 - ▶ the term “saturation” replaces the term “chroma”
 - ▶ simple conversion from gamma-corrected RGB to HSV

- ◆ designed by Alvy Ray Smith in 1978
- ◆ algorithm to convert *HSV* to *RGB* and back can be found in Foley et al., Figs 13.33 and 13.34

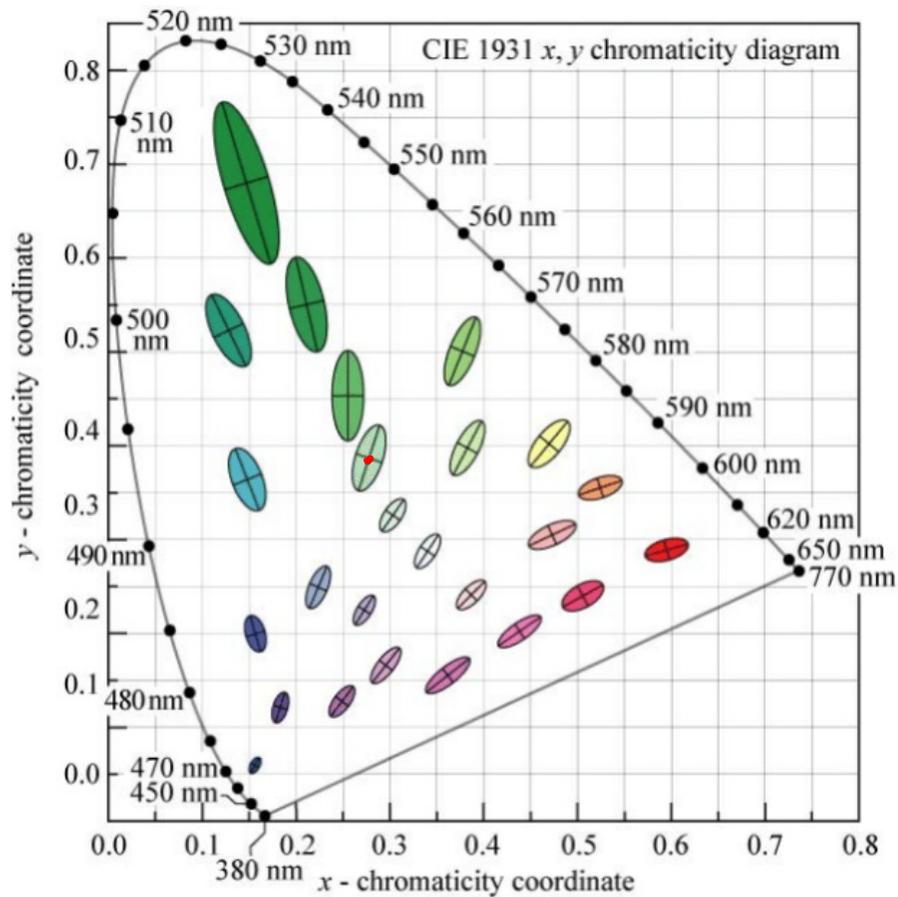

HLS: hue lightness saturation

- ★ a simple variation of *HSV*
 - ◆ hue and saturation have same meaning
 - ◆ the term “lightness” replaces the term “value”
- ★ designed to address the complaint that *HSV* has all pure colours having the same lightness/value as white
 - ◆ designed by Metrick in 1979
 - ◆ algorithm to convert *HLS* to *RGB* and back can be found in Foley et al., Figs 13.36 and 13.37

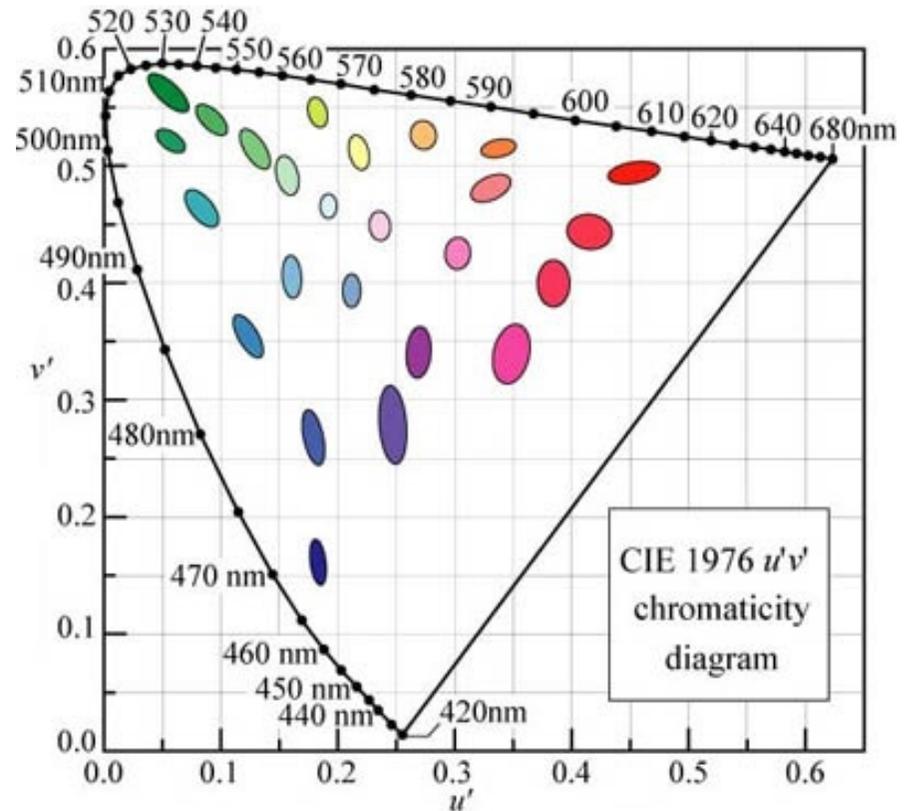

Perceptual uniformity

- ▶ MacAdam ellipses & visually indistinguishable colours

In CIE xy chromatic coordinates

In CIE $u'v'$ chromatic coordinates

CIE L*u*v* and u'v'

- ▶ Approximately perceptually uniform
- ▶ u'v' chromacity

$$u' = \frac{4X}{X + 15Y + 3Z} = \frac{4x}{-2x + 12y + 3}$$

$$v' = \frac{9Y}{X + 15Y + 3Z} = \frac{9y}{-2x + 12y + 3}$$

- ▶ CIE LUV

Lightness

$$L^* = \begin{cases} \left(\frac{29}{3}\right)^3 Y/Y_n, & Y/Y_n \leq \left(\frac{6}{29}\right)^3 \\ 116(Y/Y_n)^{1/3} - 16, & Y/Y_n > \left(\frac{6}{29}\right)^3 \end{cases}$$

Chromacity coordinates

$$u^* = 13L^* \cdot (u' - u'_n)$$

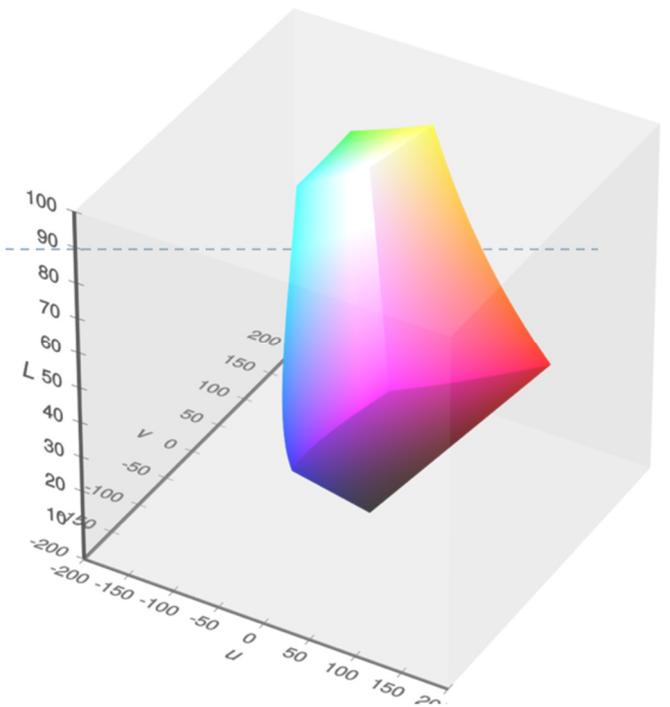

$$v^* = 13L^* \cdot (v' - v'_n)$$

Colours less distinguishable when dark

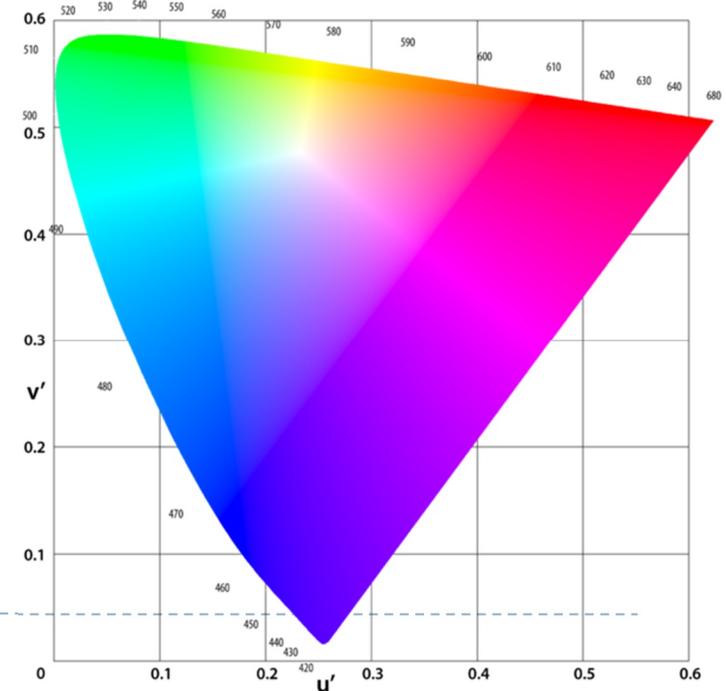

- ▶ Hue and chroma

$$C_{uv}^* = \sqrt{(u^*)^2 + (v^*)^2}$$

$$h_{uv} = \text{atan2}(v^*, u^*),$$

sRGB in CIE L*u*v*

CIE L*a*b* colour space

- ▶ Another approximately perceptually uniform colour space

$$L^* = 116f\left(\frac{Y}{Y_n}\right) - 16$$

$$a^* = 500\left(f\left(\frac{X}{X_n}\right) - f\left(\frac{Y}{Y_n}\right)\right)$$

$$b^* = 200\left(f\left(\frac{Y}{Y_n}\right) - f\left(\frac{Z}{Z_n}\right)\right)$$

$$f(t) = \begin{cases} \sqrt[3]{t} & \text{if } t > \delta^3 \\ \frac{t}{3\delta^2} + \frac{4}{29} & \text{otherwise} \end{cases}$$

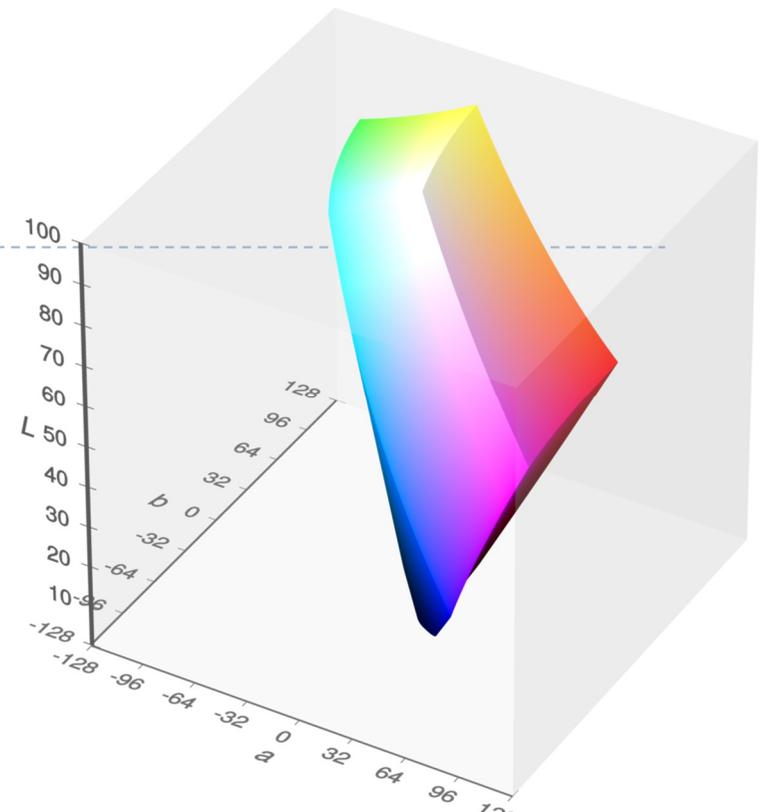

$$\delta = \frac{6}{29}$$

Trichromatic values of the white point, e.g.

$$X_n = 95.047,$$

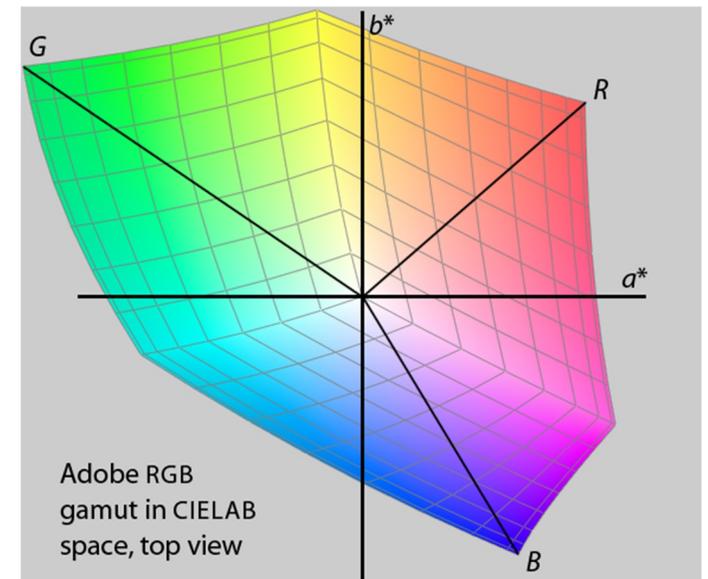

$$Y_n = 100.000,$$

$$Z_n = 108.883$$

- ▶ Chroma and hue

$$C^* = \sqrt{a^{*2} + b^{*2}}, \quad h^\circ = \arctan\left(\frac{b^*}{a^*}\right)$$

Lab space

- ▶ this visualization shows those colours in *Lab* space which a human can perceive
- ▶ again we see that human perception of colour is not uniform
 - ▶ perception of colour diminishes at the white and black ends of the L axis
 - ▶ the maximum perceivable chroma differs for different hues

The smallest detectable luminance difference

Background (adapting) luminance

$$\frac{\Delta L}{L} = k$$

Constant

Typical stimuli:

Consequence of the Weber-law

- ▶ Smallest detectable difference in luminance

$$\frac{\Delta L}{L} = k$$

For k=1%

L	ΔL
100 cd/m ²	1 cd/m ²
1 cd/m ²	0.01 cd/m ²

- ▶ Adding or subtracting luminance will have different visual impact depending on the background luminance
- ▶ Unlike LDR luma values, luminance values are **not** perceptually uniform!

How to make luminance (more) perceptually uniform?

- ▶ Using “Fechnerian” integration

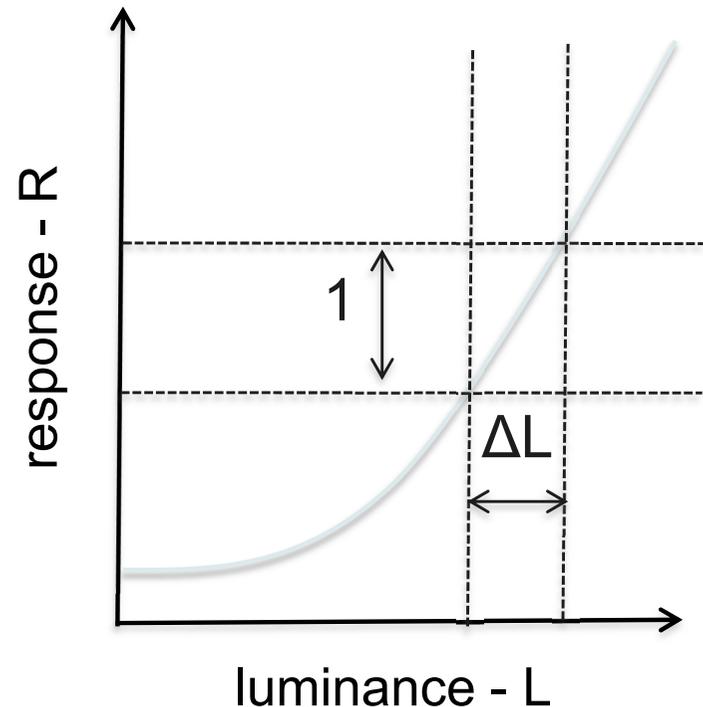

$$\frac{dR}{dl}(L) = \frac{1}{\Delta L(L)}$$

Derivative of response

Detection threshold

Luminance transducer:

$$R(L) = \int_{L_{min}}^L \frac{1}{\Delta L(l)} dl$$

Assuming the Weber law

$$\frac{\Delta L}{L} = k$$

- ▶ and given the luminance transducer

$$R(L) = \int \frac{1}{\Delta L(l)} dl$$

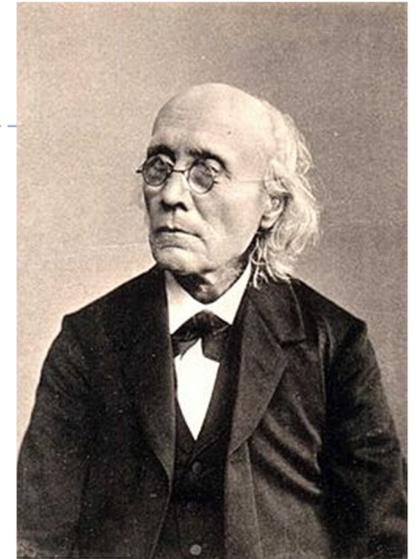

- ▶ the response of the visual system to light is:

$$R(L) = \int \frac{1}{kL} dL = \frac{1}{k} \ln(L) + k_1$$

Fechner law

$$R(L) = a \ln(L)$$

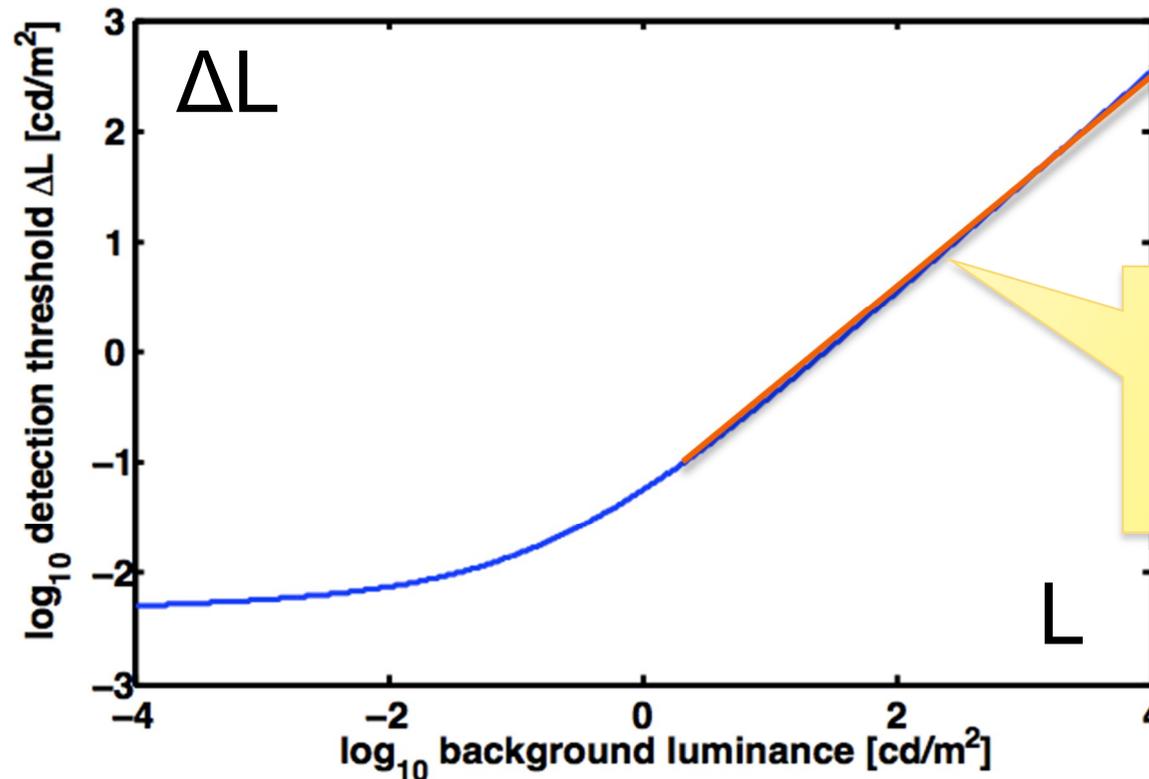

- ▶ Response of the visual system to luminance is **approximately** logarithmic

Gustav Fechner
[From Wikipedia]

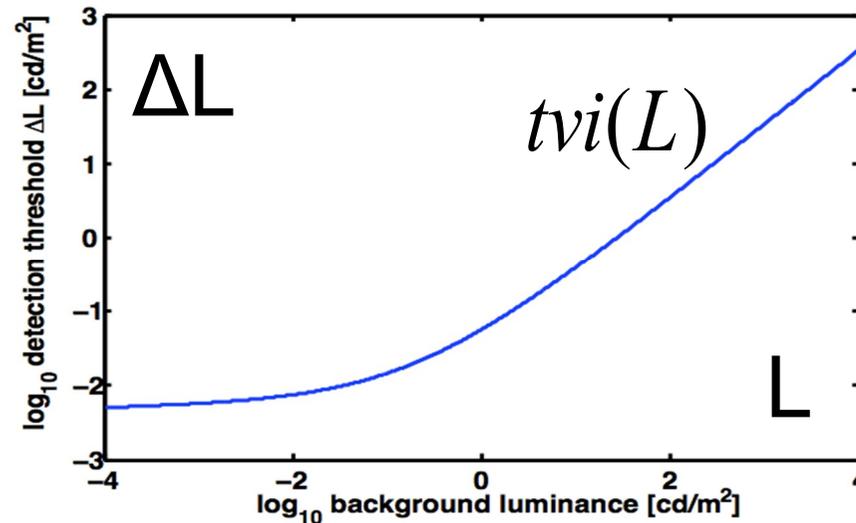

But...the Fechner law does not hold for the full luminance range

- ▶ Because the Weber law does not hold either
- ▶ Threshold vs. intensity function:

Weber-law revisited

- ▶ If we allow detection threshold to vary with luminance according to the t.v.i. function:

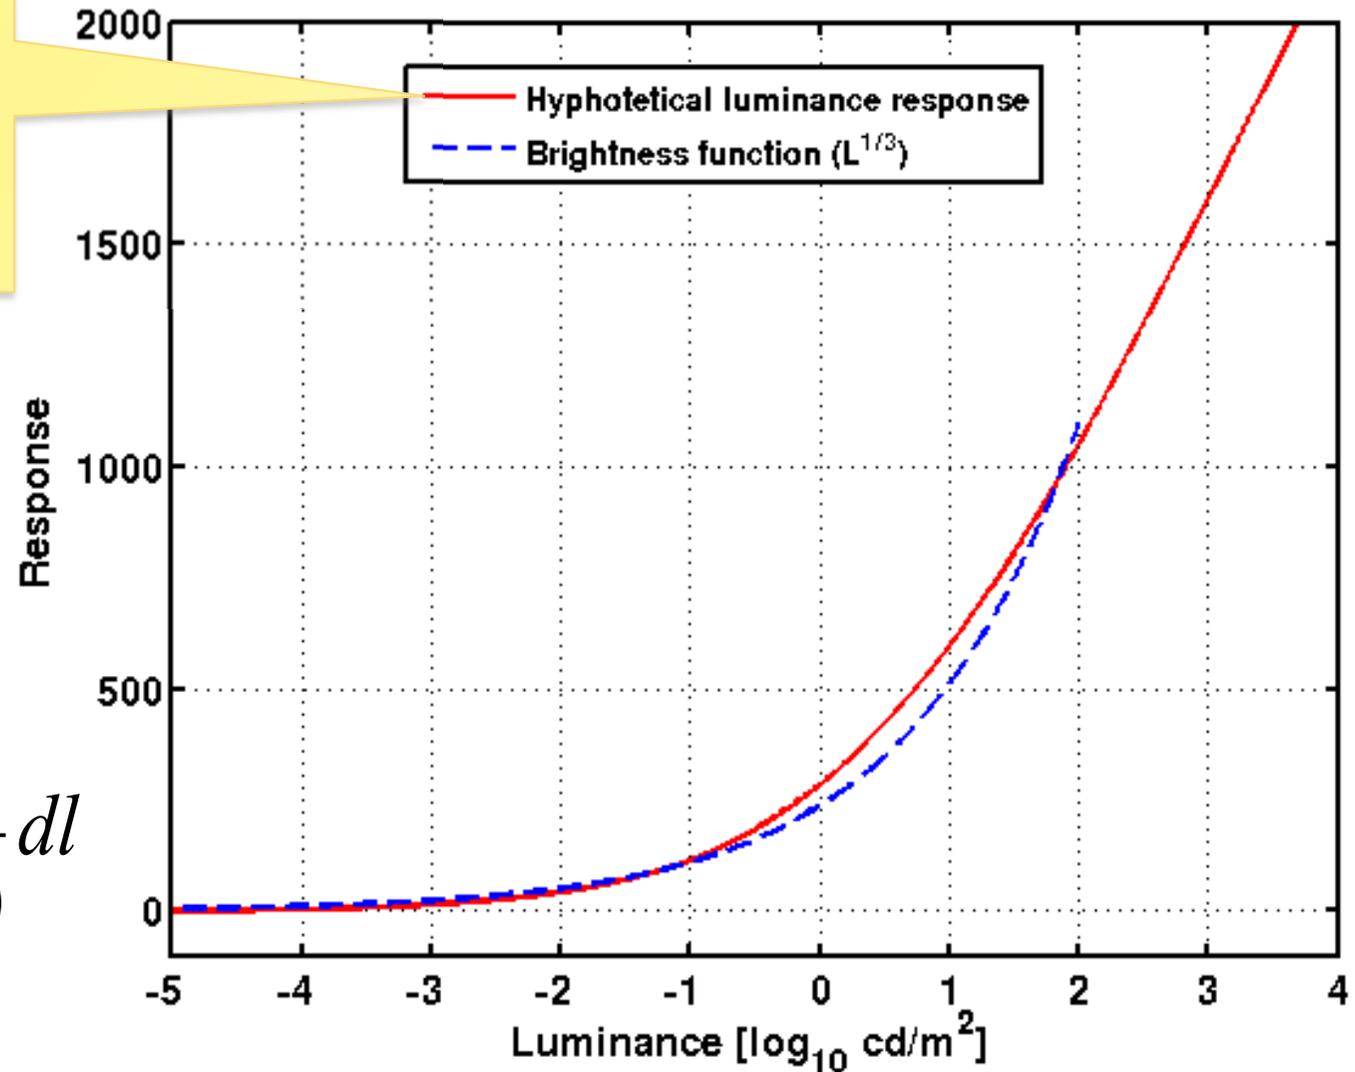

- ▶ we can get a more accurate estimate of the “response”:

$$R(L) = \int_0^L \frac{1}{tvi(l)} dl$$

Fechnerian integration and Stevens' law

R(L) - function derived from the t.v.i. function

$$R(L) = \int_0^L \frac{1}{tvi(l)} dl$$

Applications of JND encoding – R(L)

- ▶ **DICOM grayscale function**
 - ▶ Function used to encode signal for medical monitors
 - ▶ 10-bit JND-scaled (just noticeable difference)
 - ▶ Equal visibility of gray levels
- ▶ **HDMI 2.0a (HDR10)**
 - ▶ PQ (Perceptual Quantizer) encoding
 - ▶ Dolby Vision
 - ▶ To encode pixels for high dynamic range images and video

The Future of Vision

Advanced Graphics and Image Processing

Models of early visual perception

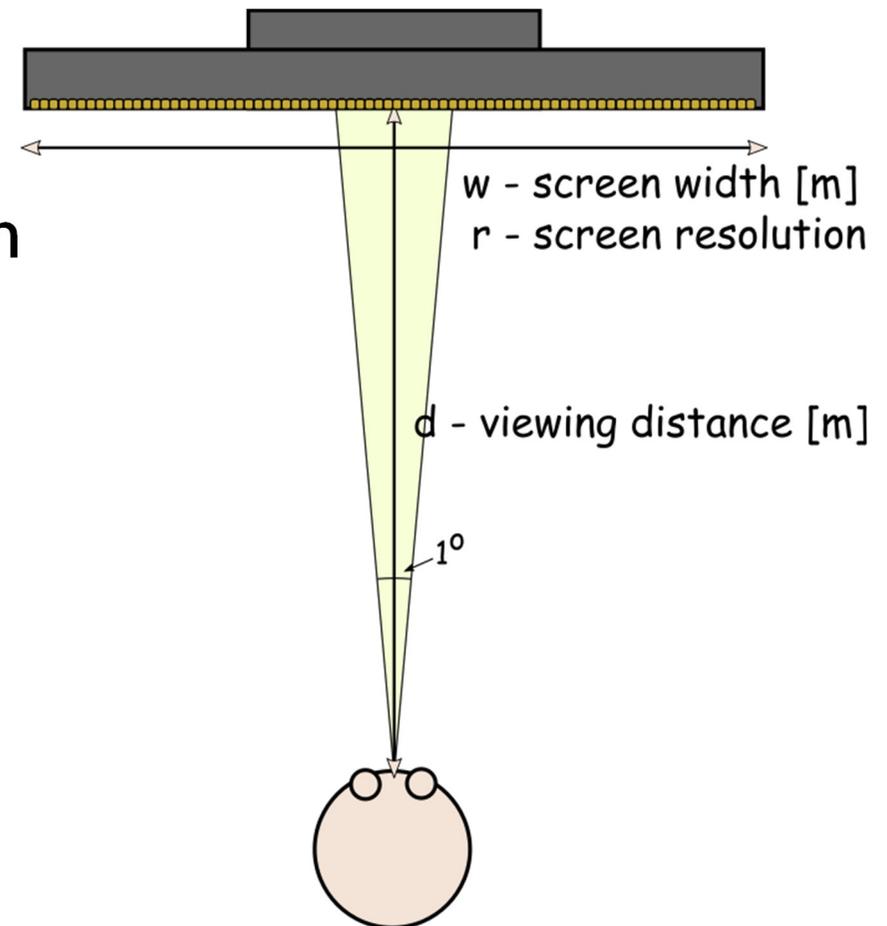

Part 3/6 – spatial contrast sensitivity and contrast constancy

Rafal Mantiuk

Computer Laboratory, University of Cambridge

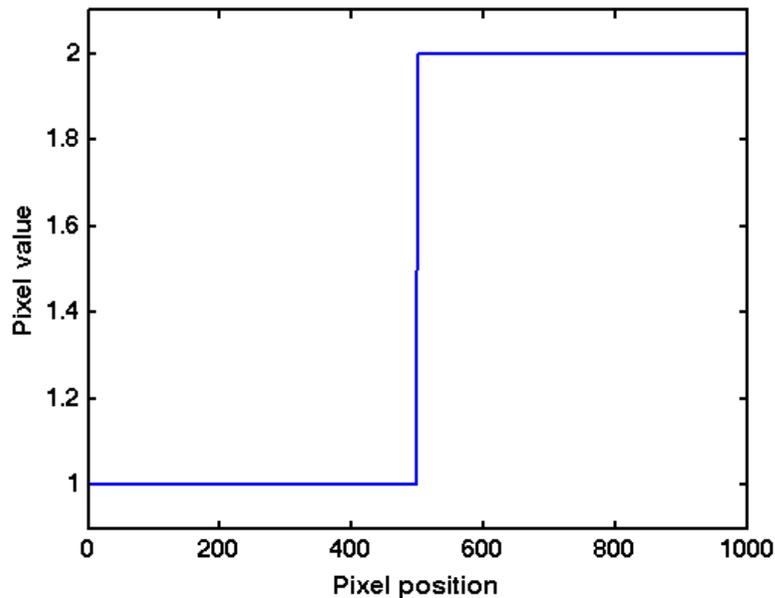

Resolution and sampling rate

- ▶ **Pixels per inch [ppi]**
 - ▶ Does not account for vision
- ▶ **The visual resolution depends on**
 - ▶ screen size
 - ▶ screen resolution
 - ▶ viewing distance
- ▶ **The right measure**
 - ▶ Pixels per visual degree [ppd]
 - ▶ In frequency space
 - ▶ Cycles per visual degree [cpd]

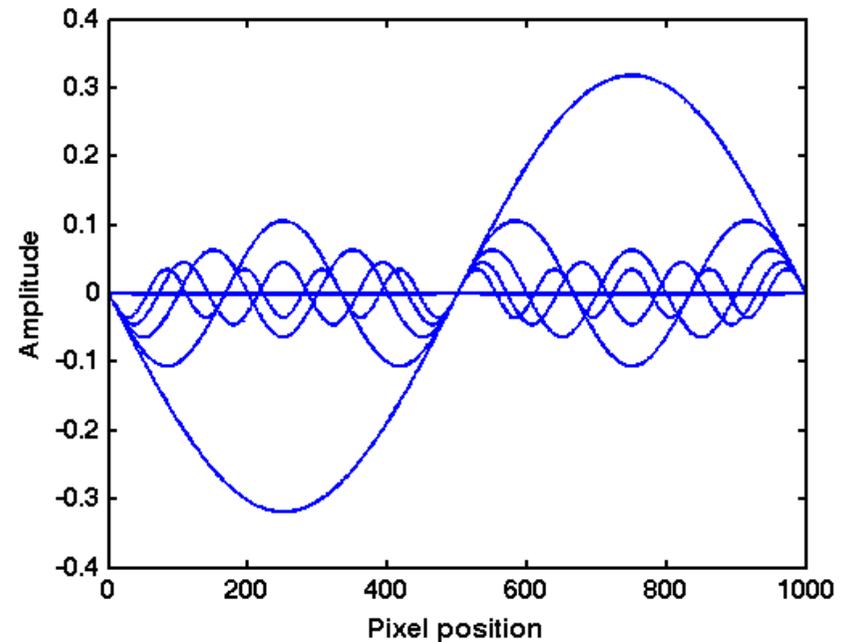

Fourier analysis

- ▶ Every N-dimensional function (including images) can be represented as a sum of sinusoidal waves of different frequency and phase

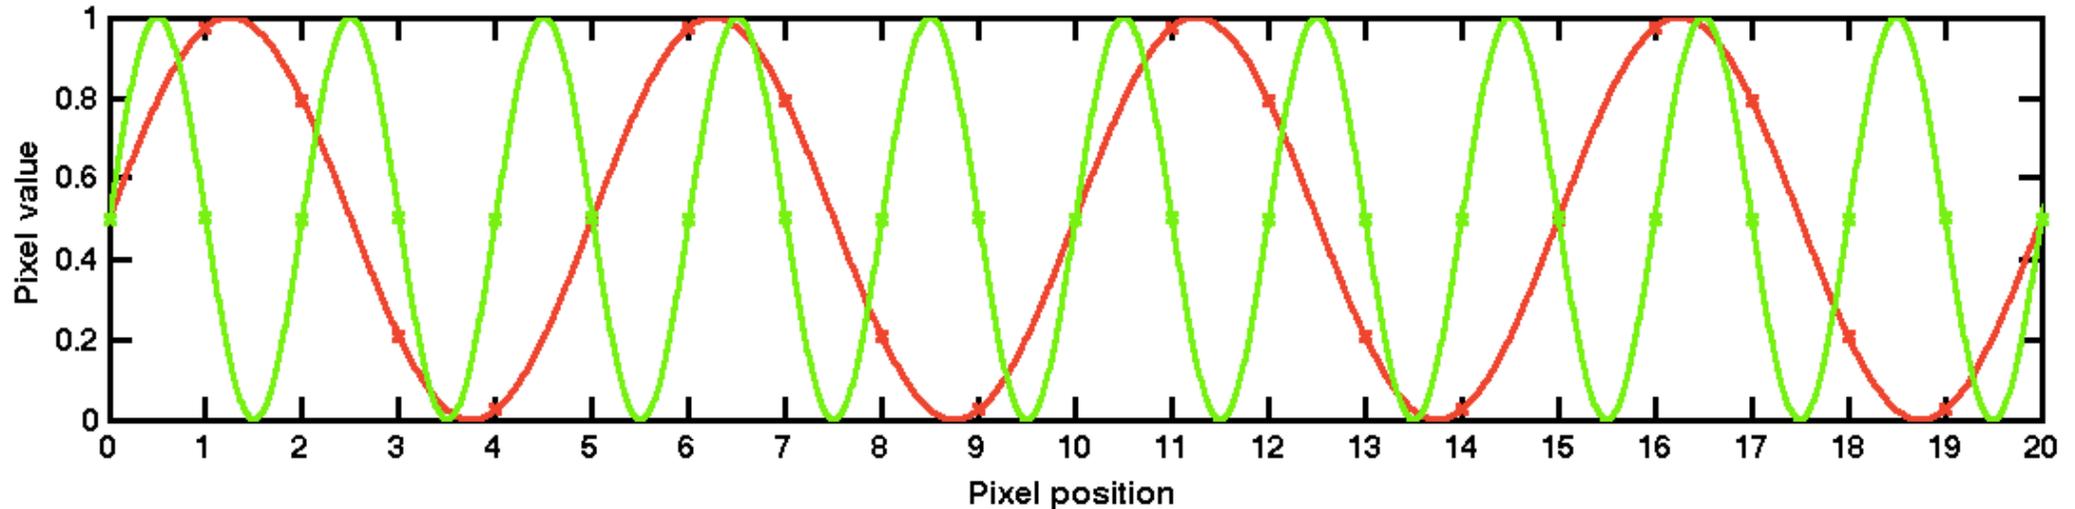

$$= \Sigma$$

- ▶ Think of “equalizer” in audio software, which manipulates each frequency

Spatial frequency in images

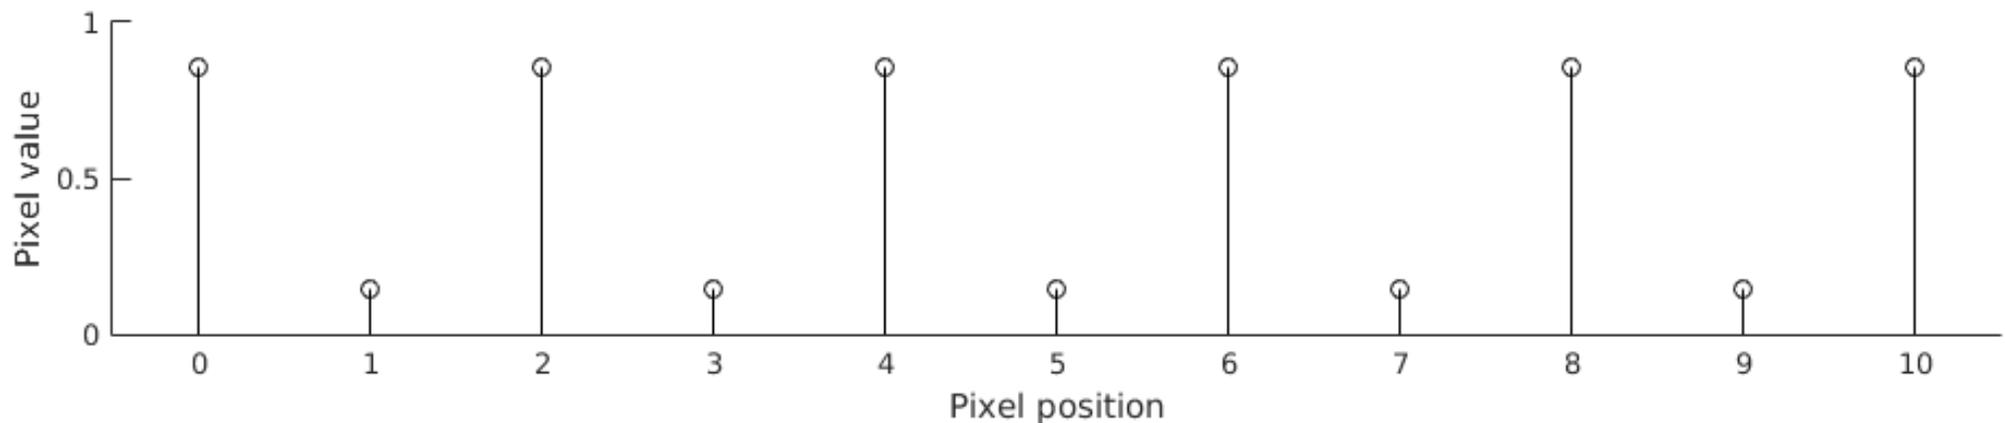

- ▶ Image space units: cycles per sample (or cycles per pixel)

- ▶ What are the screen-space frequencies of the red and green sinusoid?
- ▶ The visual system units: cycles per degree
 - ▶ If the angular resolution of the viewed image is 55 pixels per degree, what is the frequency of the sinusoids in cycles per degree?

Nyquist frequency

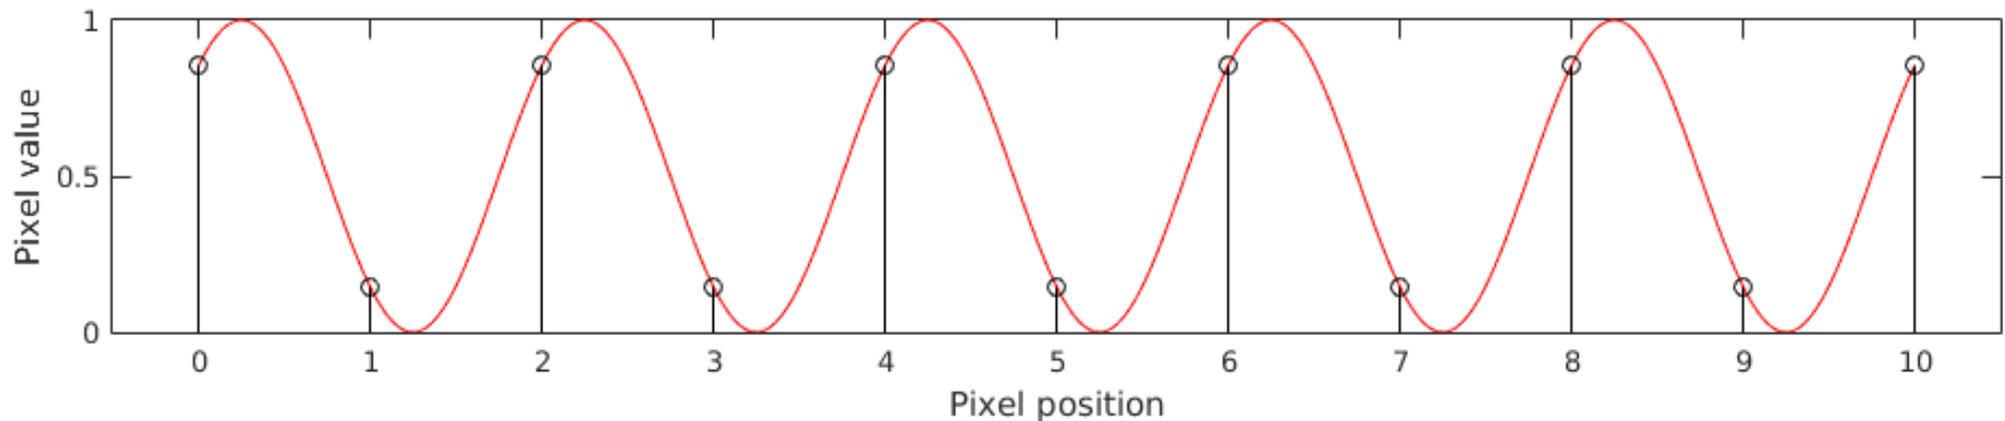

- ▶ Sampling density restricts the highest spatial frequency signal that can be (uniquely) reconstructed
 - ▶ Sampling density – how many pixels per image/visual angle/...

- ▶ Any number of sinusoids can be fitted to this set of samples
- ▶ It is possible to fit an infinite number of sinusoids if we allow infinitely high frequency

Nyquist frequency

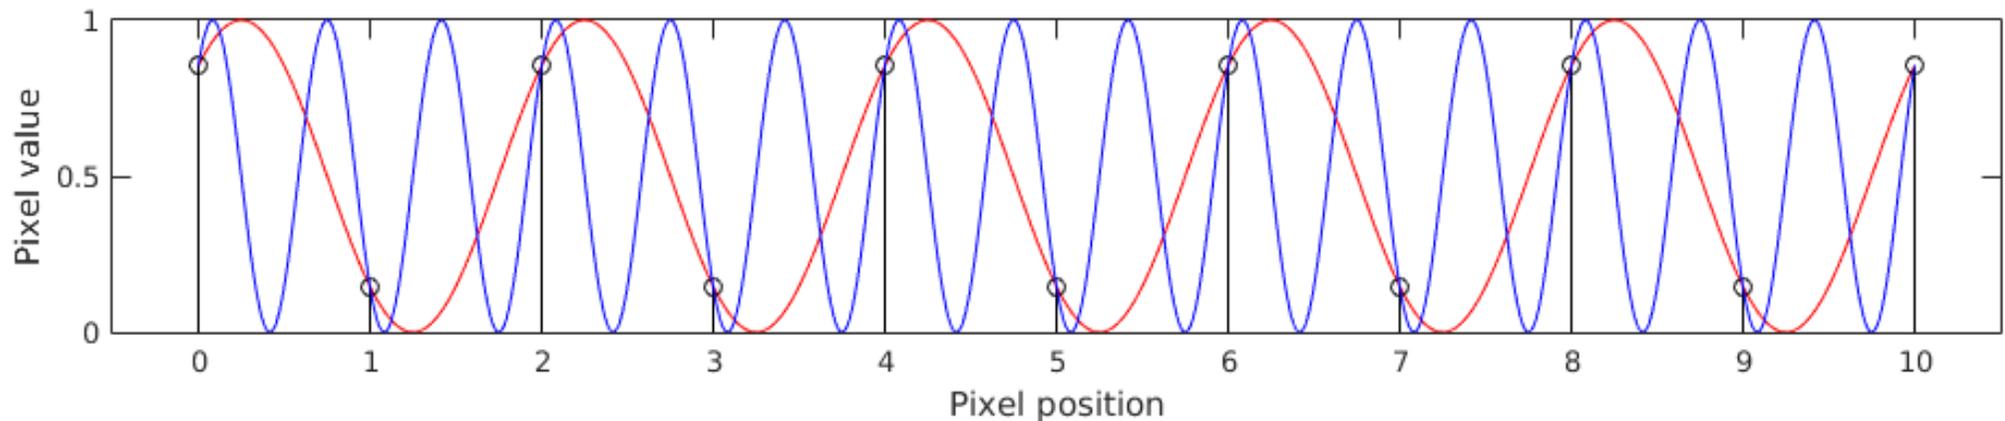

- ▶ Sampling density restricts the highest spatial frequency signal that can be (uniquely) reconstructed
 - ▶ Sampling density – how many pixels per image/visual angle/...

- ▶ Any number of sinusoids can be fitted to this set of samples
- ▶ It is possible to fit an infinite number of sinusoids if we allow infinitely high frequency

Nyquist frequency

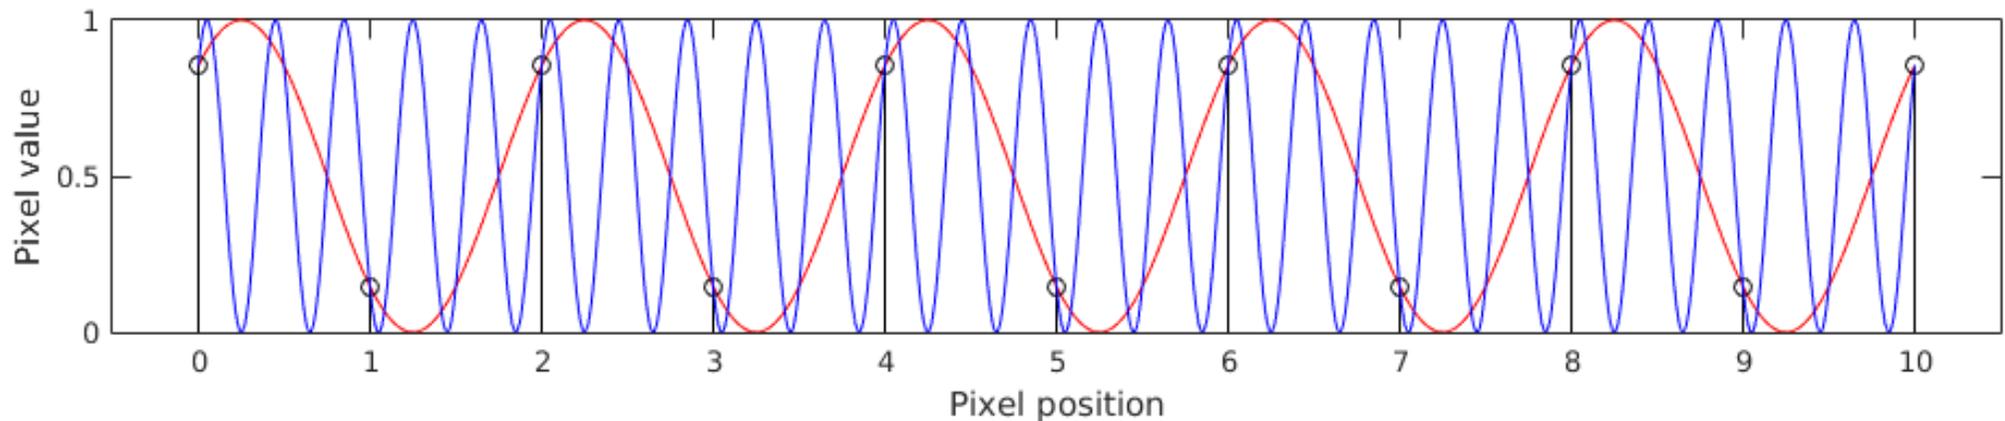

- ▶ Sampling density restricts the highest spatial frequency signal that can be (uniquely) reconstructed
 - ▶ Sampling density – how many pixels per image/visual angle/...

- ▶ Any number of sinusoids can be fitted to this set of samples
- ▶ It is possible to fit an infinite number of sinusoids if we allow infinitely high frequency

Nyquist frequency

- ▶ Sampling density restricts the highest spatial frequency signal that can be (uniquely) reconstructed
 - ▶ Sampling density – how many pixels per image/visual angle/...

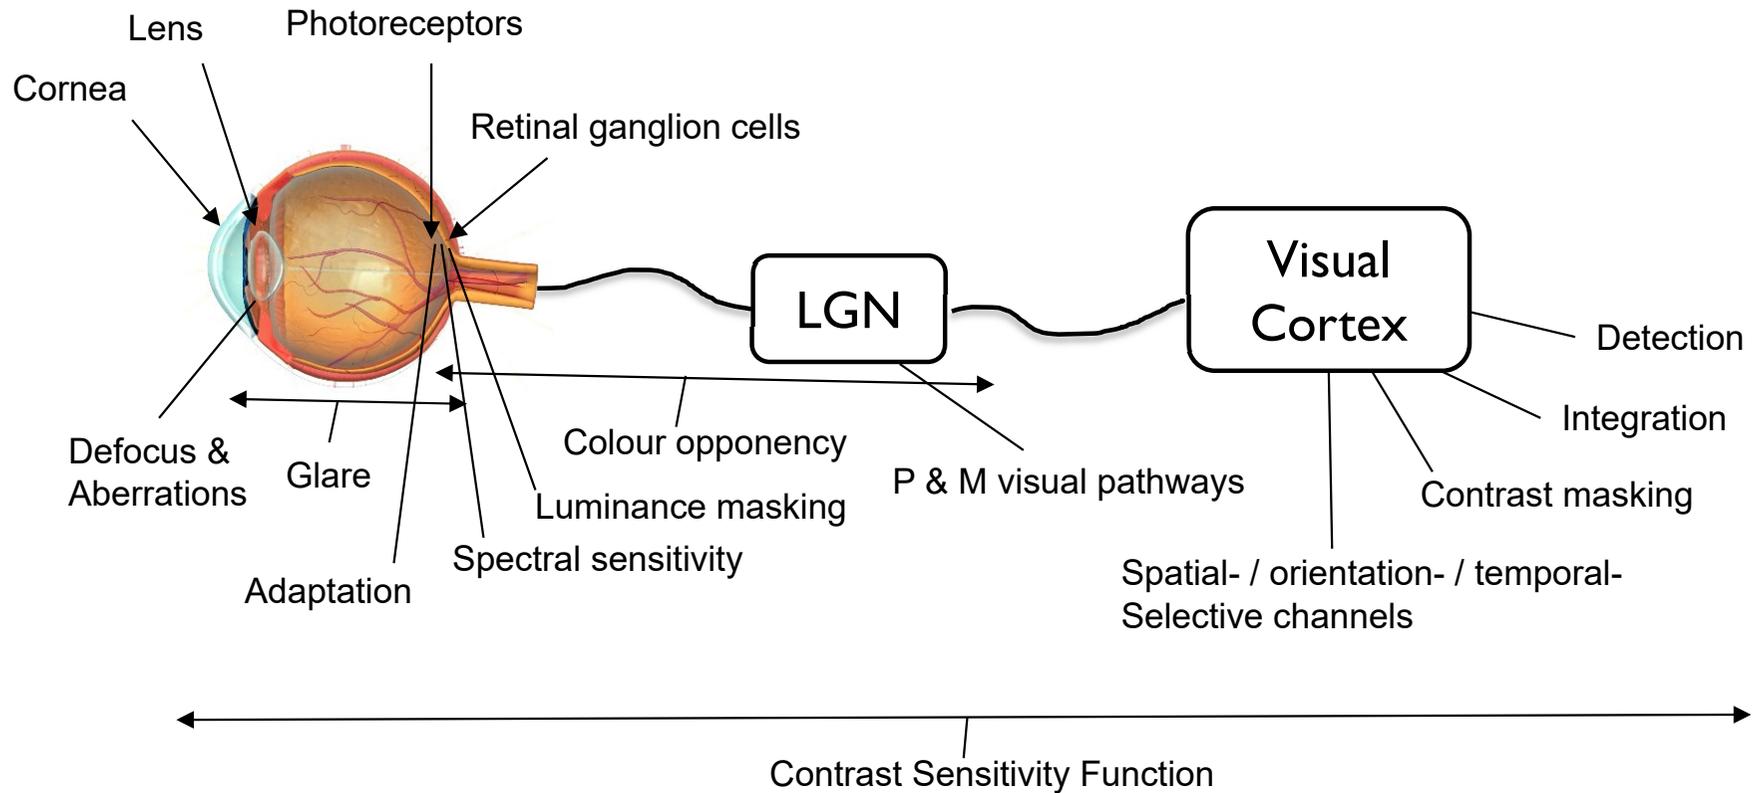

- ▶ Any number of sinusoids can be fitted to this set of samples
- ▶ It is possible to fit an infinite number of sinusoids if we allow infinitely high frequency

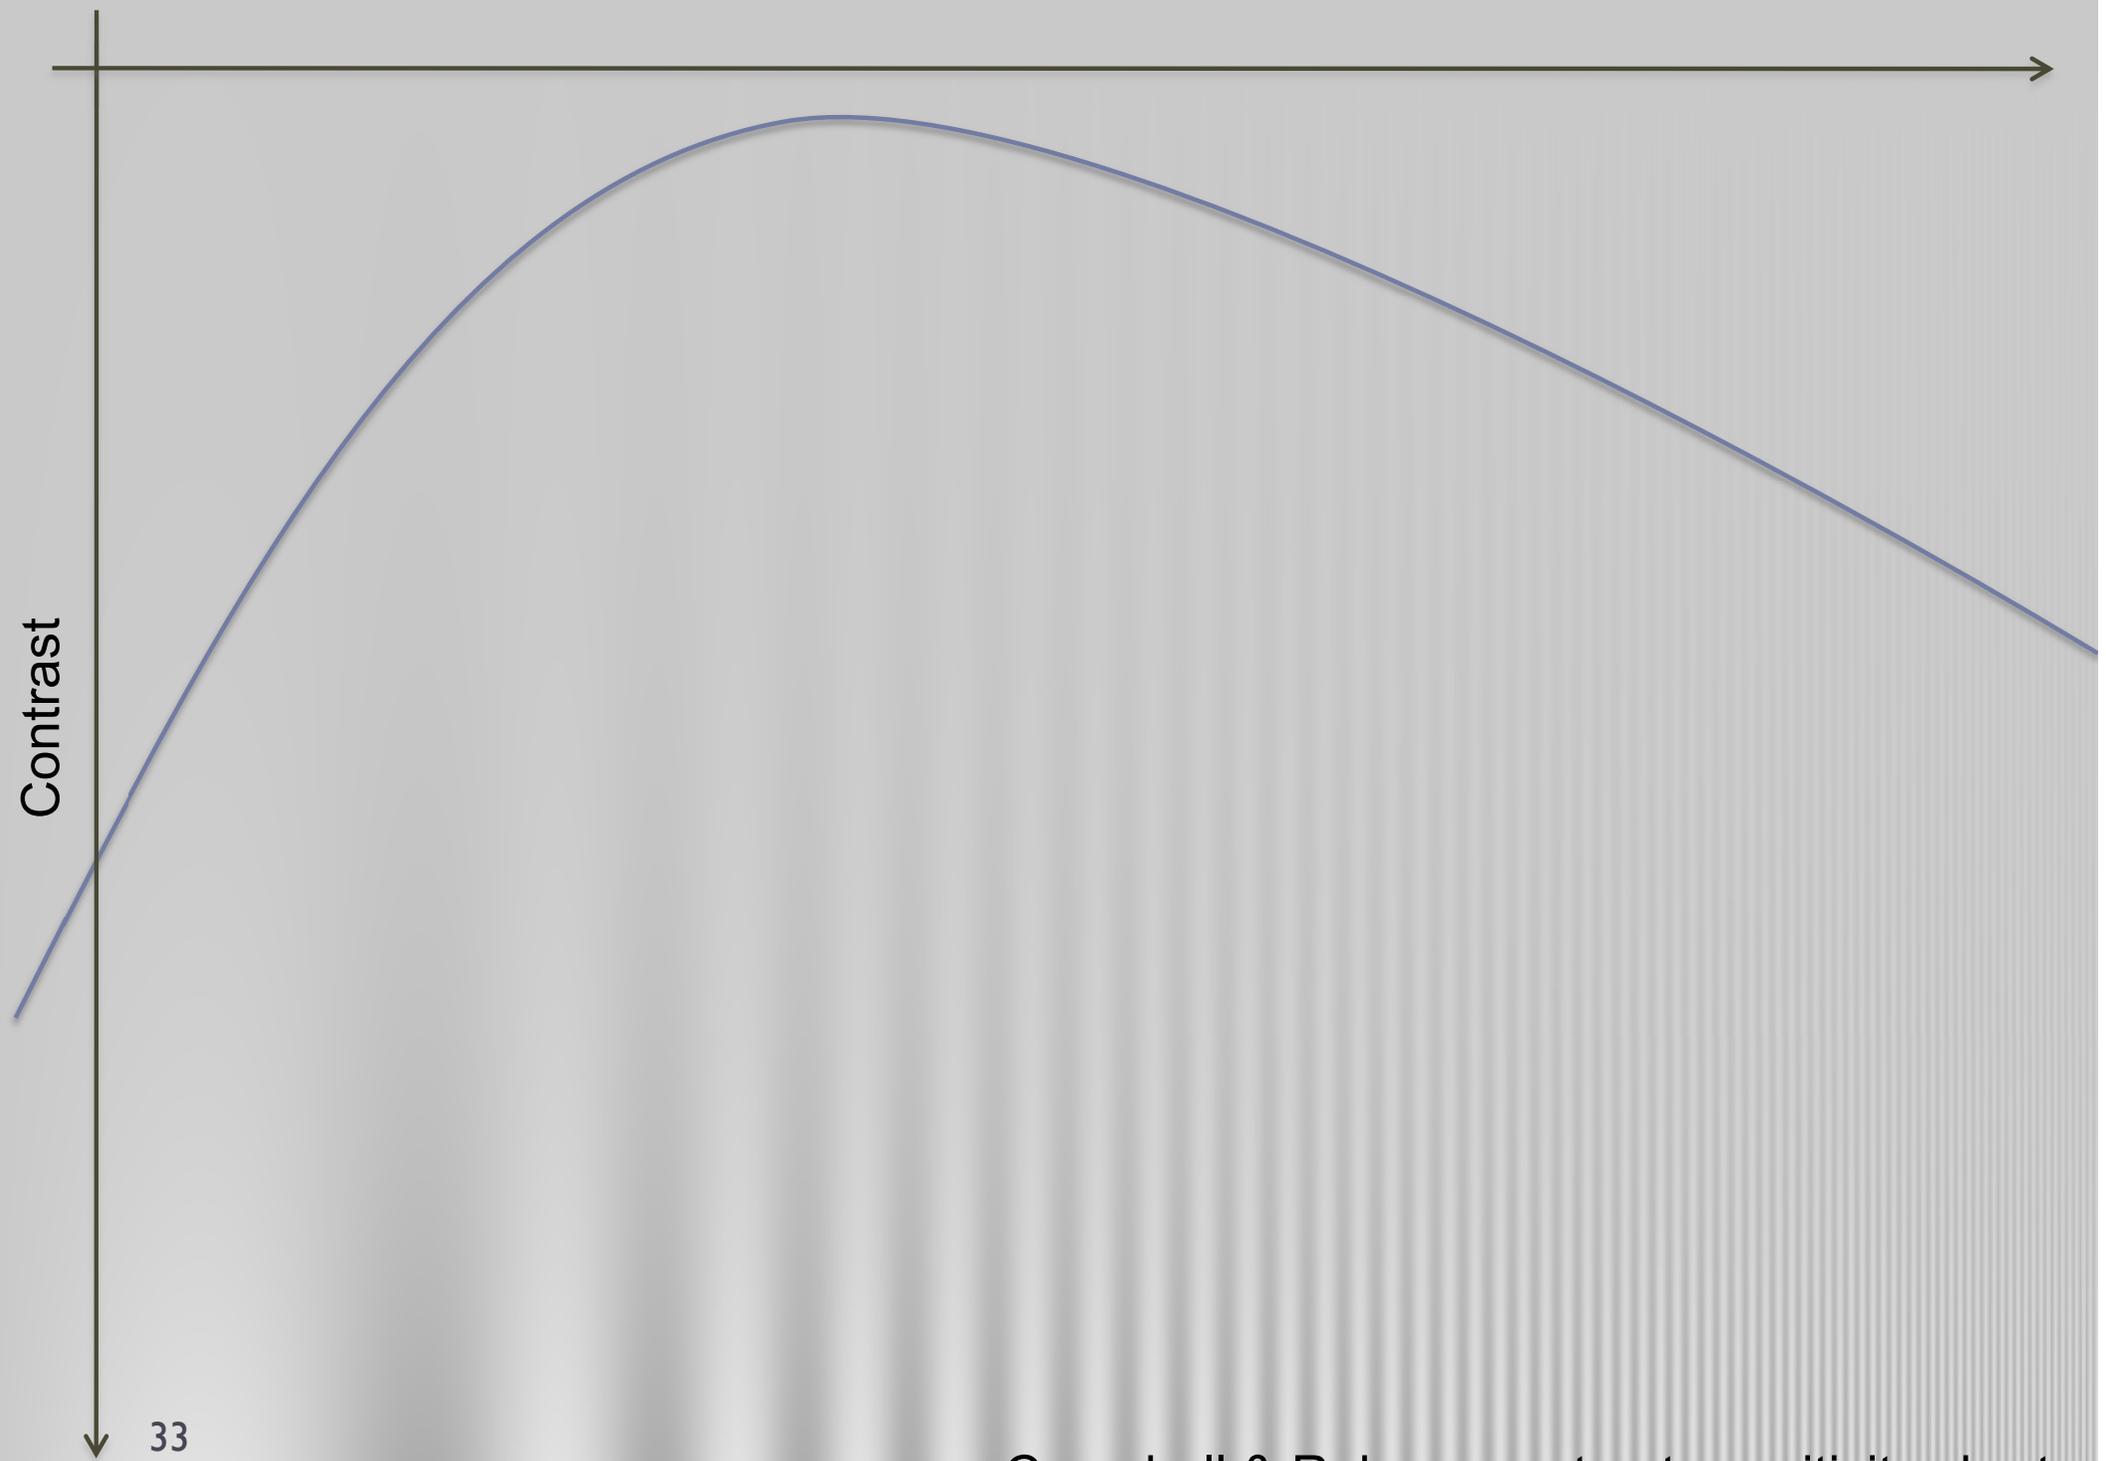

Nyquist frequency / aliasing

- ▶ Nyquist frequency is the highest frequency that can be represented by a discrete set of uniform samples (pixels)
- ▶ Nyquist frequency = 0.5 sampling rate
 - ▶ For audio
 - ▶ If the sampling rate is 44100 samples per second (audio CD), then the Nyquist frequency is 22050 Hz
 - ▶ For images (visual degrees)
 - ▶ If the sampling rate is 60 pixels per degree, then the Nyquist frequency is 30 cycles per degree
- ▶ When resampling an image to lower resolution, the frequency content above the Nyquist frequency needs to be removed (reduced in practice)
 - ▶ Otherwise **aliasing** is visible

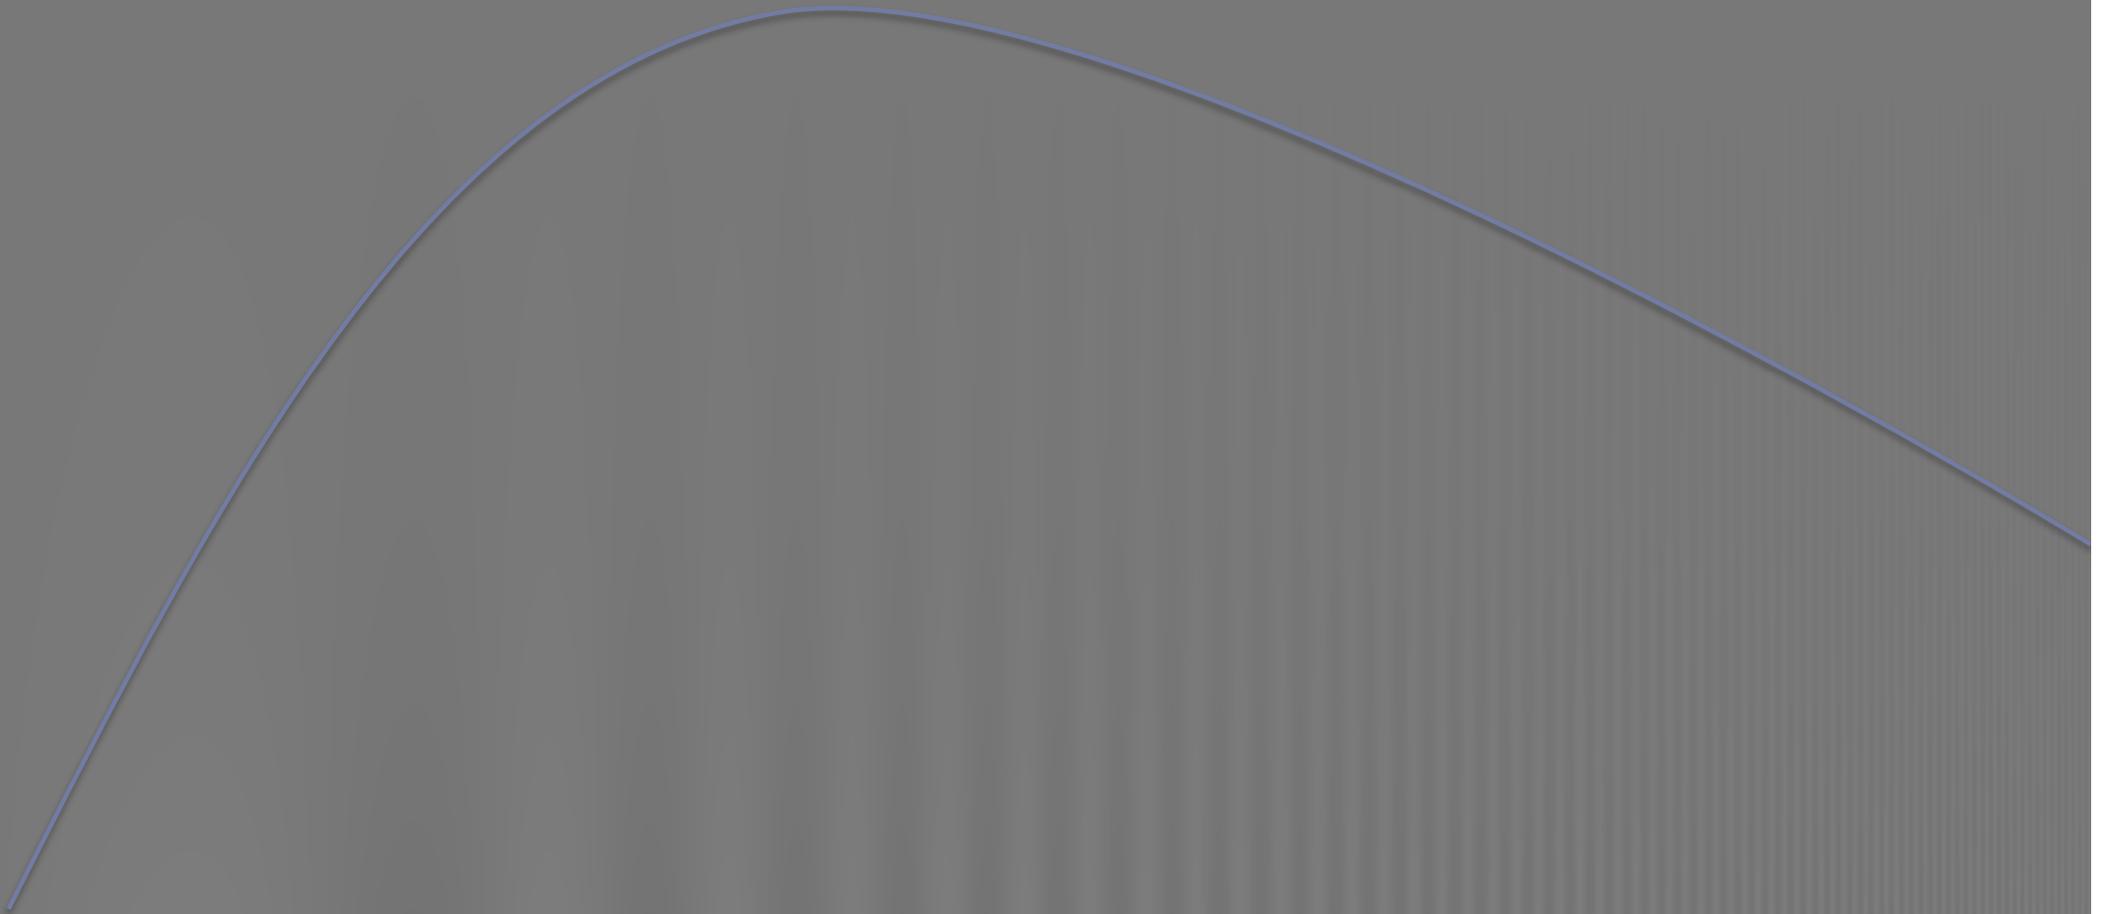

Modeling contrast detection

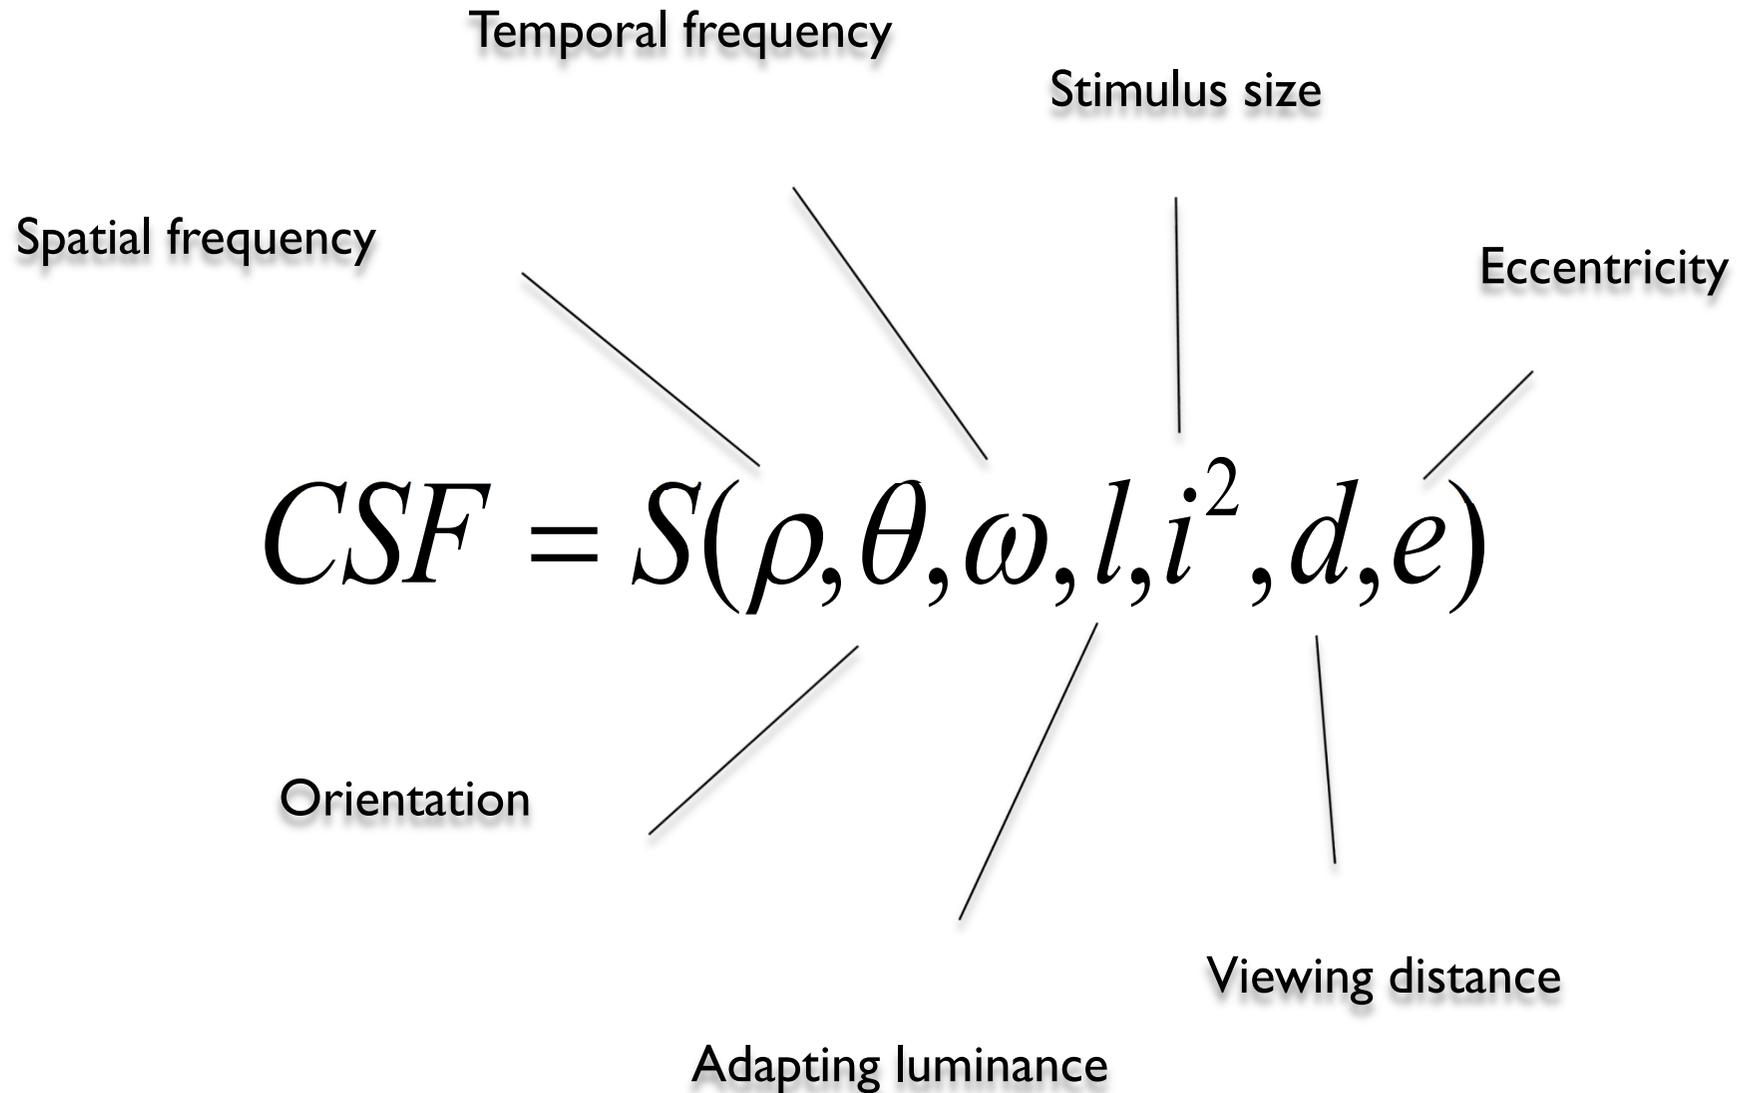

Spatial frequency [cycles per degree]

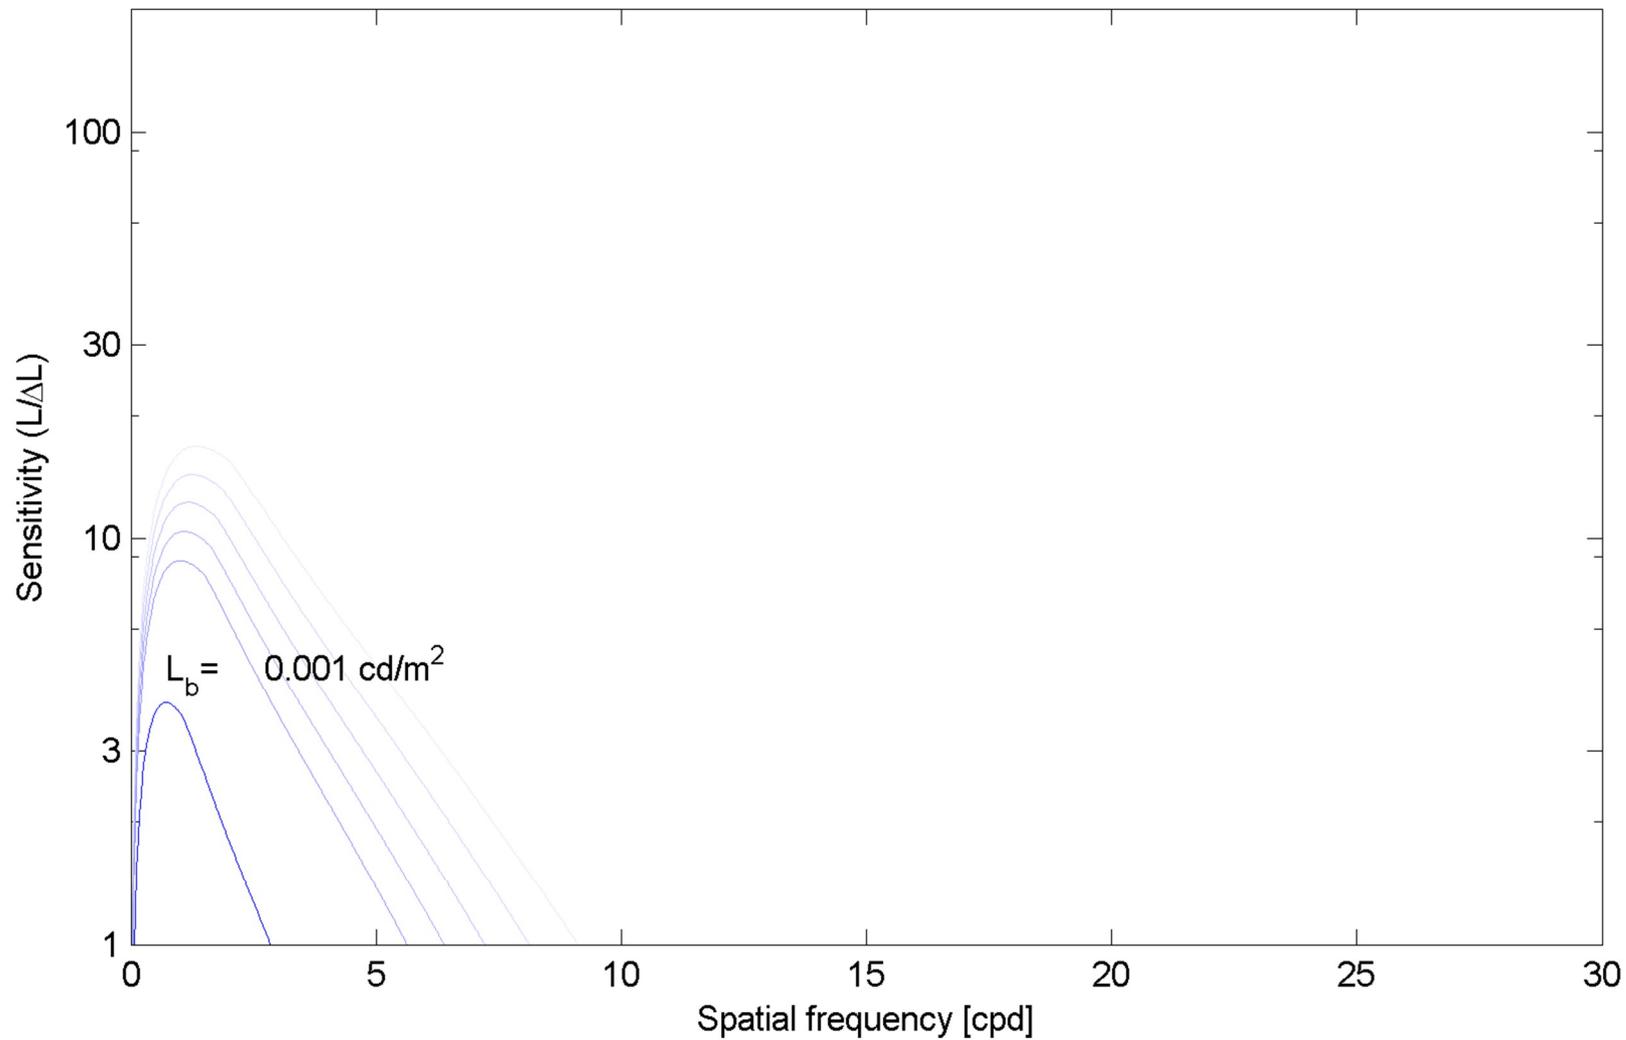

Campbell & Robson contrast sensitivity chart

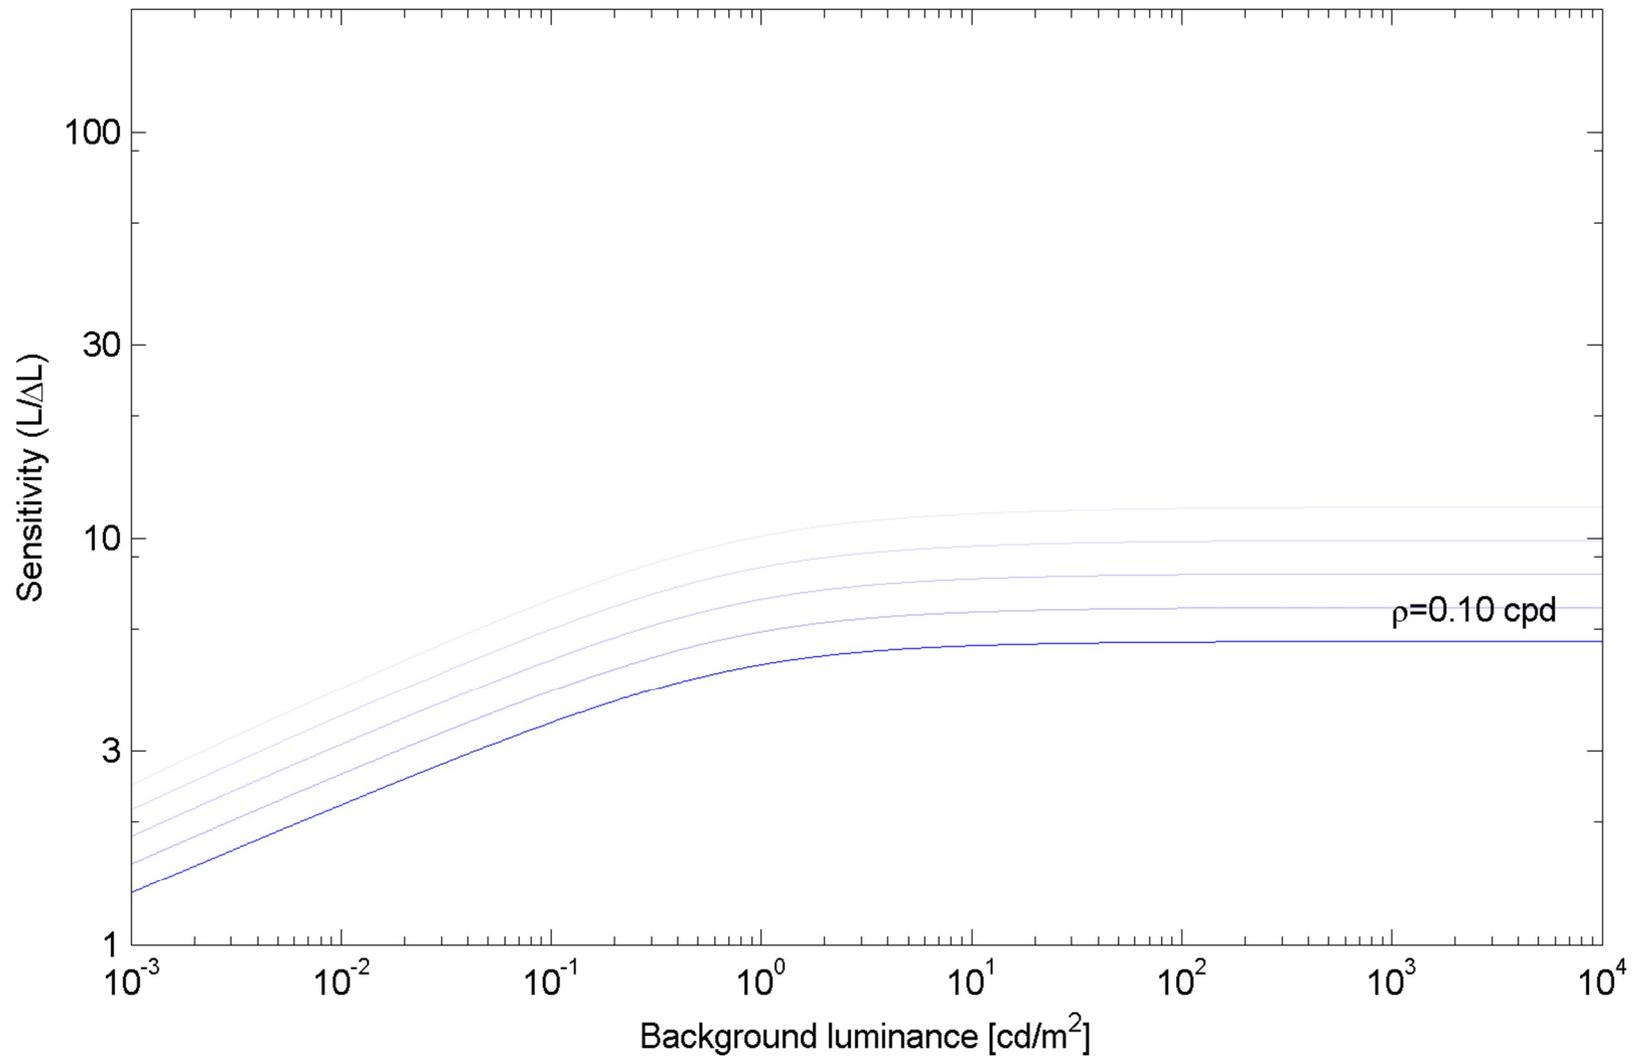

Contrast sensitivity function

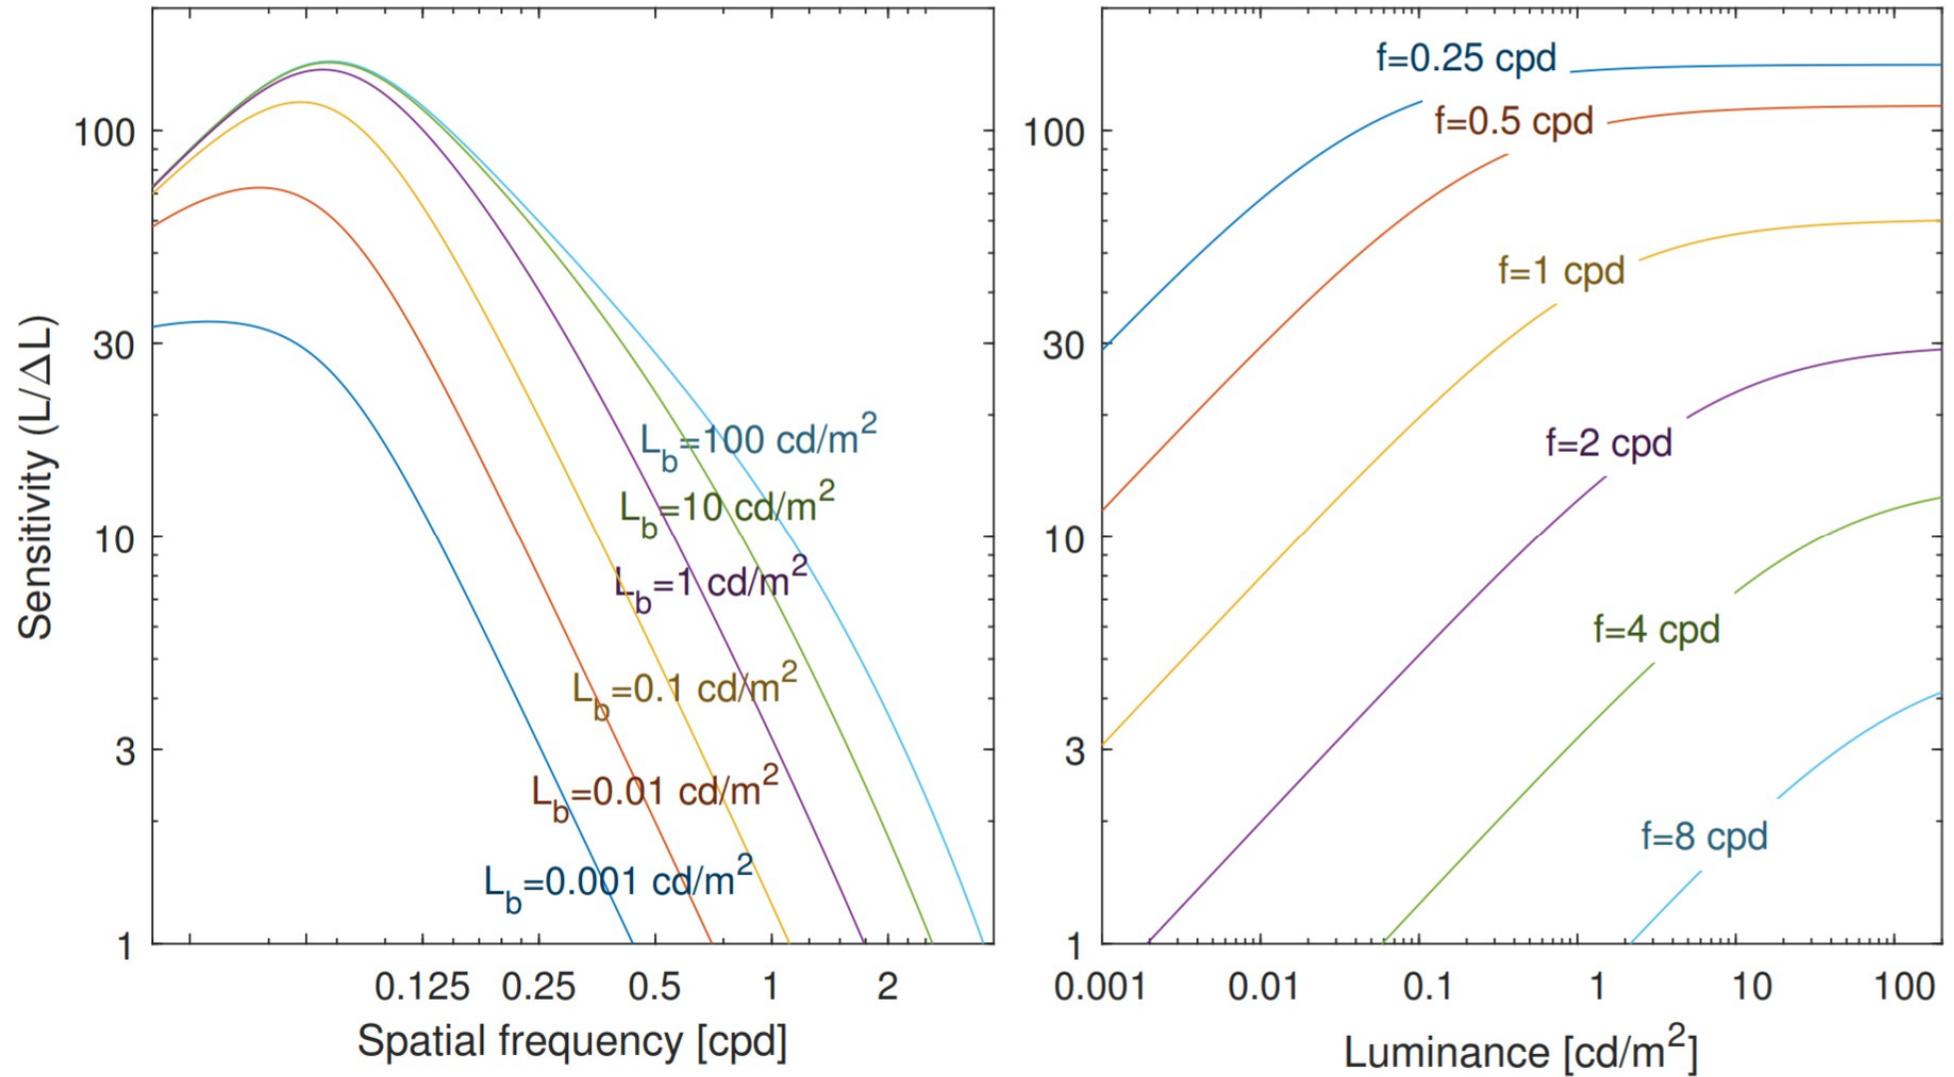

CSF as a function of spatial frequency

CSF as a function of background luminance

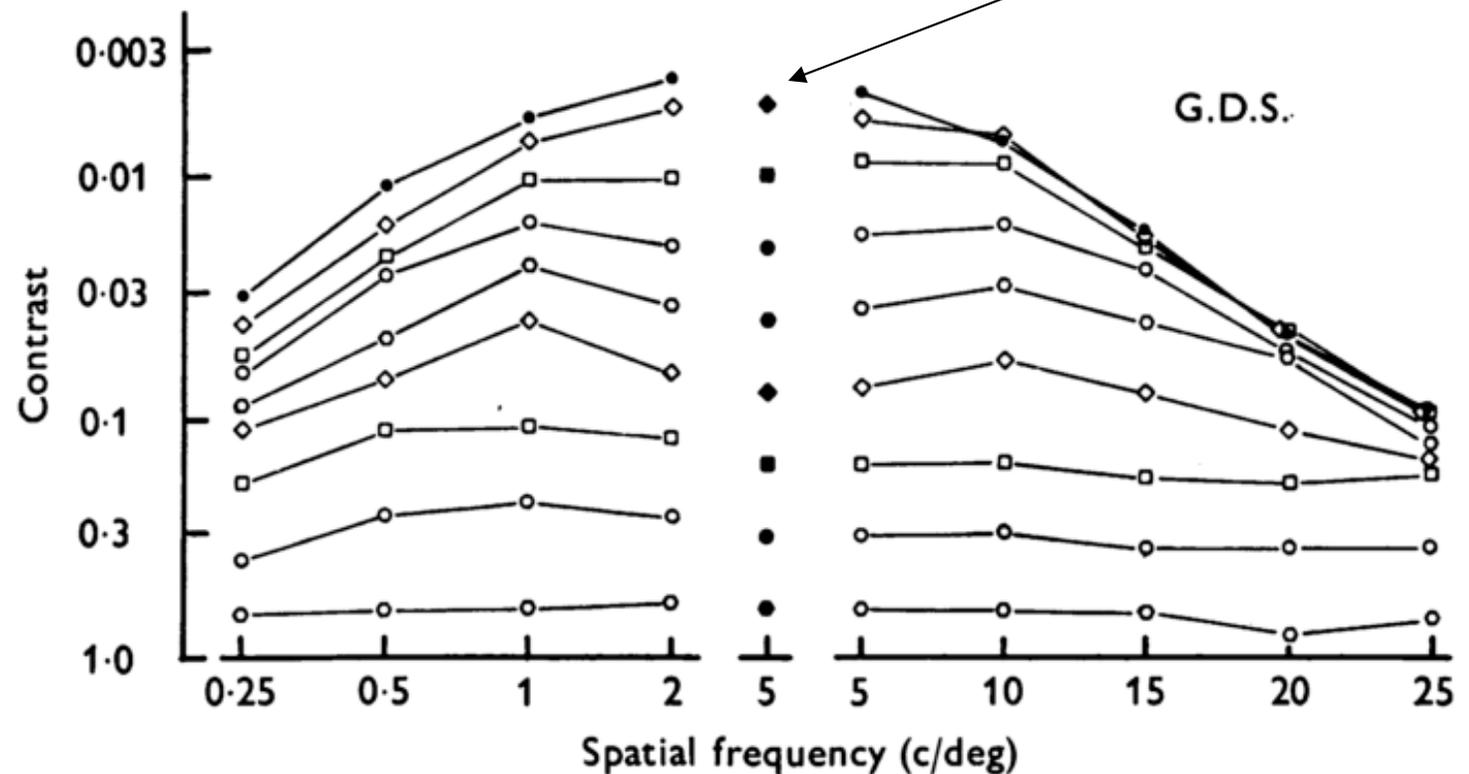

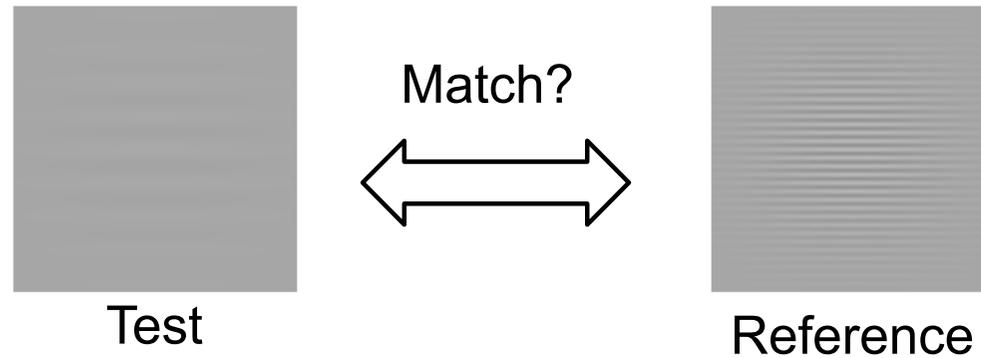

CSF as a function of spatial frequency and background luminance

Contrast constancy

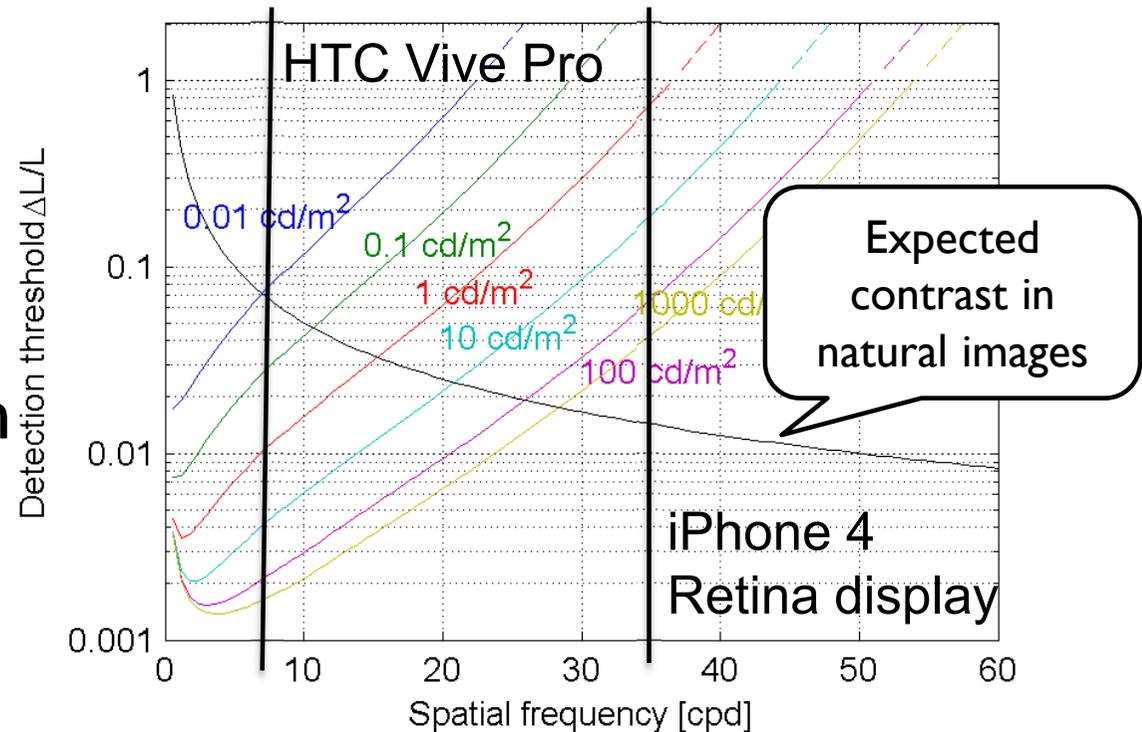

Experiment: Adjust the amplitude of one sinusoidal grating until it matches the perceived magnitude of another sinusoidal grating.

Contrast constancy
No CSF above the detection threshold

CSF and the resolution

- ▶ CSF plotted as the detection contrast
$$\frac{\Delta L}{L_b} = S^{-1}$$
- ▶ The contrast below each line is invisible
- ▶ Maximum perceivable resolution depends on luminance

CSF models:

Barten, P. G. J. (2004).

<https://doi.org/10.1117/12.537476>

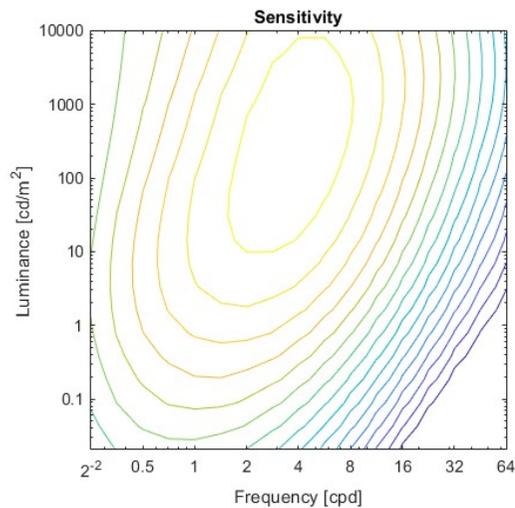

Spatio-chromatic CSF

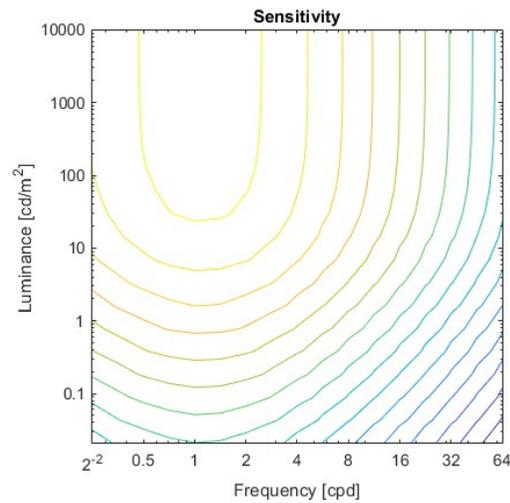

Spatio-chromatic contrast sensitivity

- ▶ CSF as a function of **luminance** and **frequency**

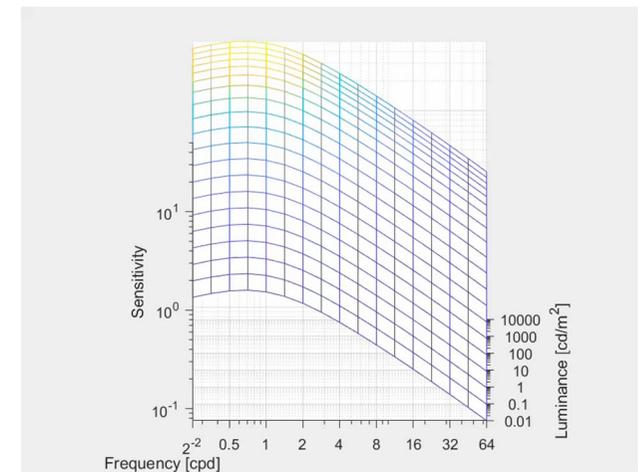

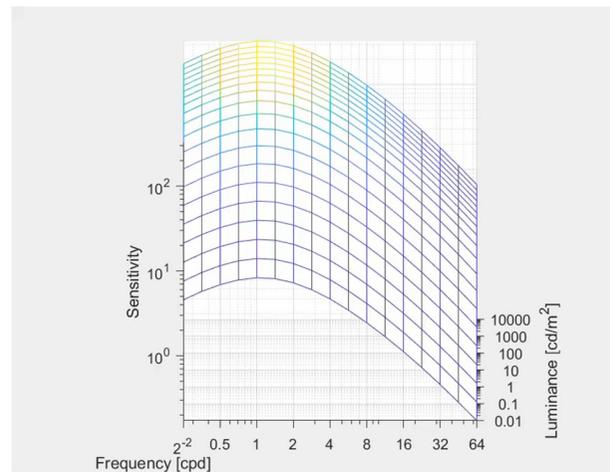

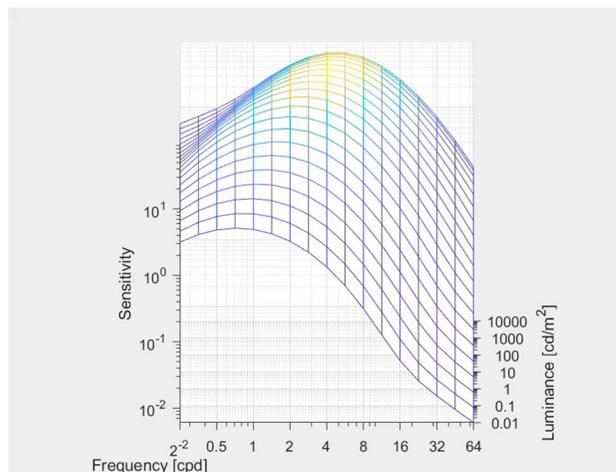

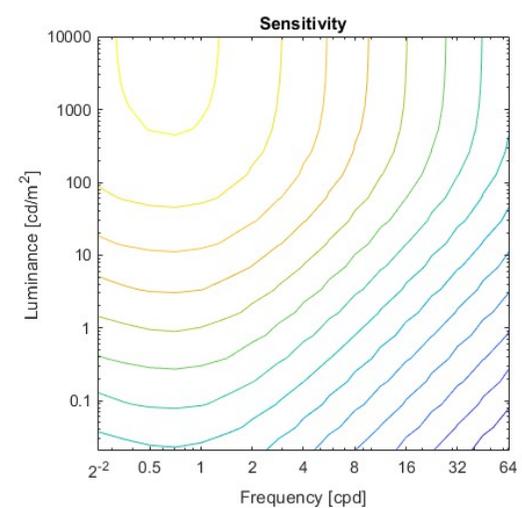

Black-White

Red-Green

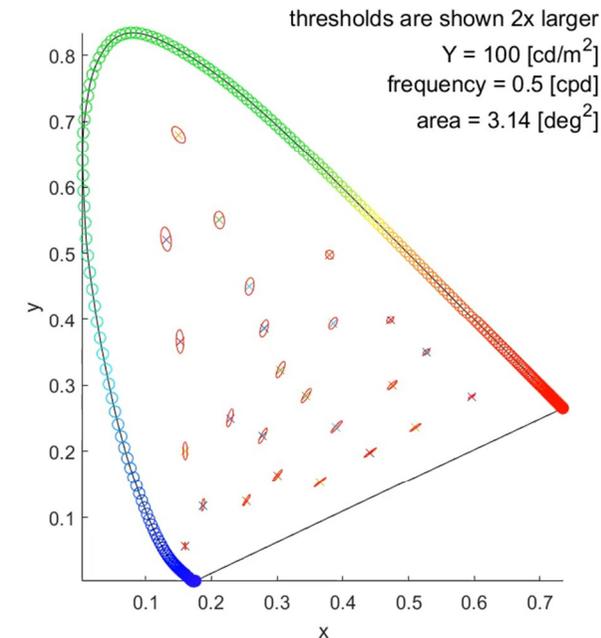

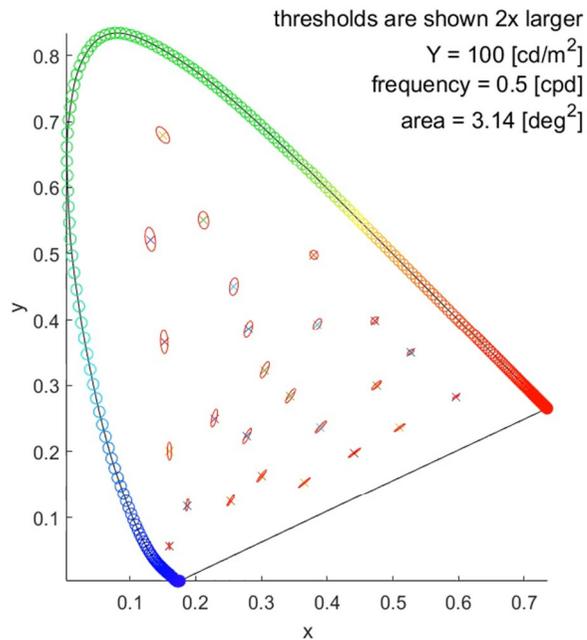

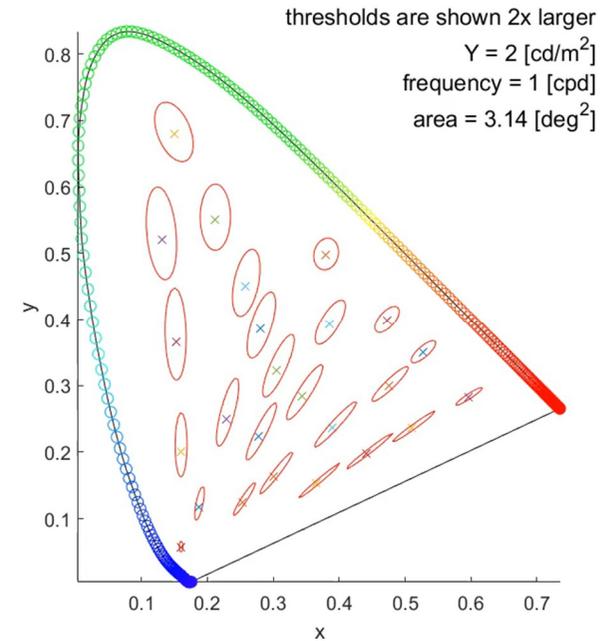

Violet-Yellow

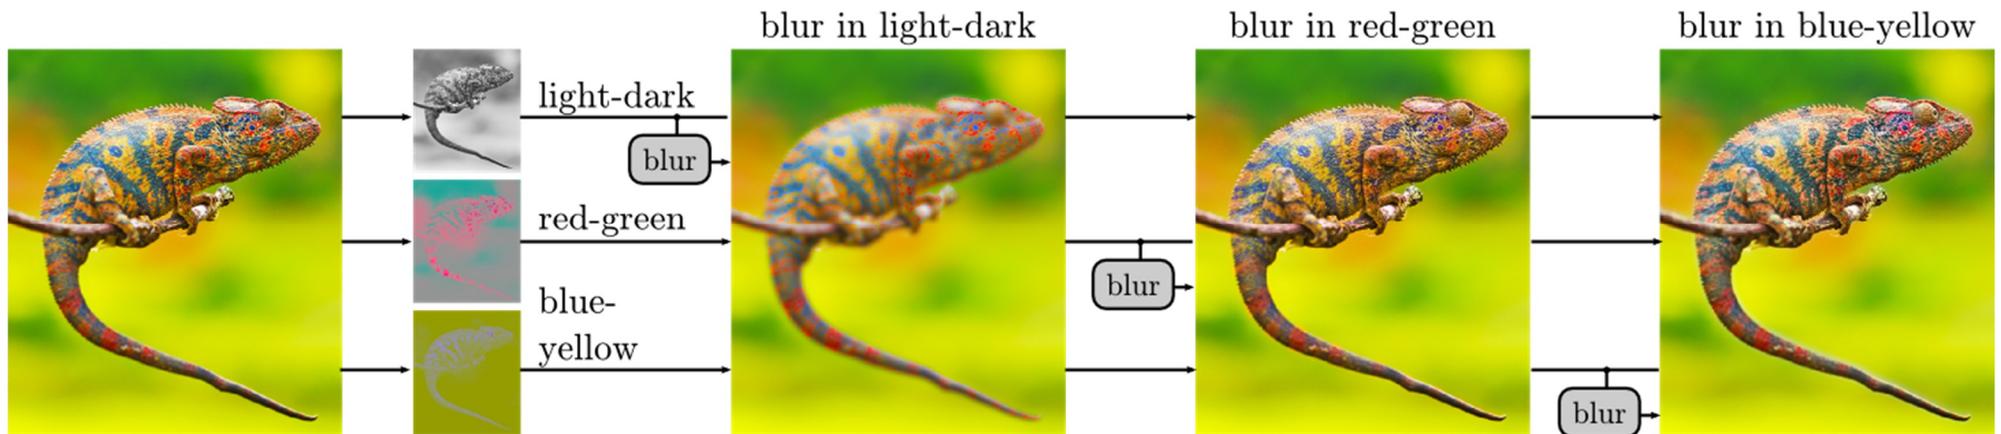

CSF and colour ellipses

- Colour discrimination as a function of
 - Background colour and luminance [LMS]
 - Spatial frequency [cpd]
 - Size [deg]

Visibility of blur

- ▶ The same amount of blur was introduced into light-dark, red-green and blue-yellow colour opponent channels
- ▶ The blur is only visible in light-dark channel
- ▶ This property is used in image and video compression
 - ▶ Sub-sampling of colour channels (4:2:1)

Advanced Graphics and Image Processing

Models of early visual perception

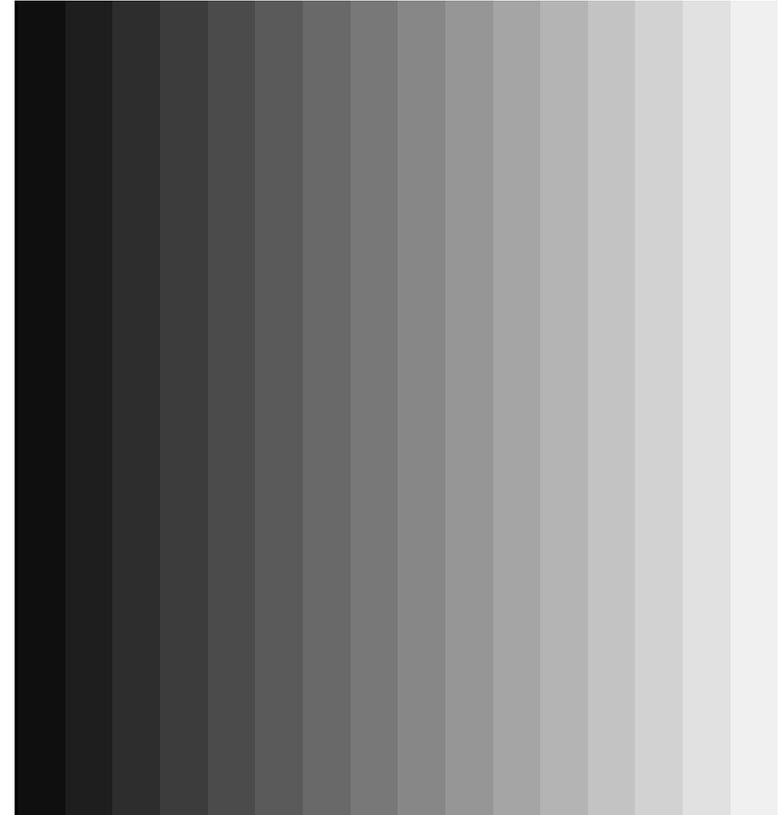

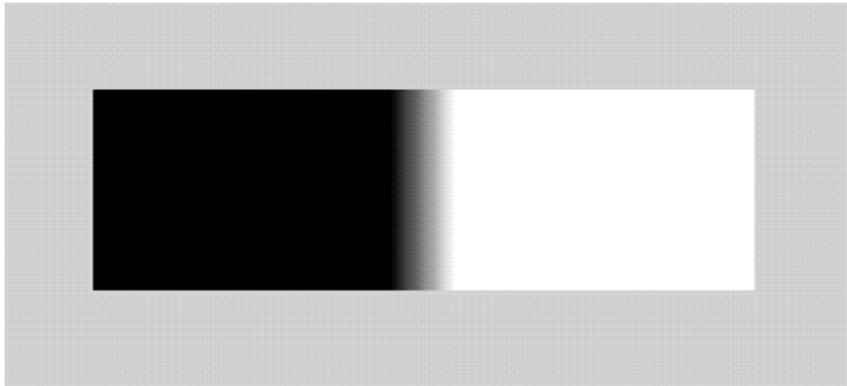

Part 4/6 – lateral inhibition and multi-resolution models

Rafal Mantiuk

Computer Laboratory, University of Cambridge

Mach Bands – evidence for band-pass visual processing

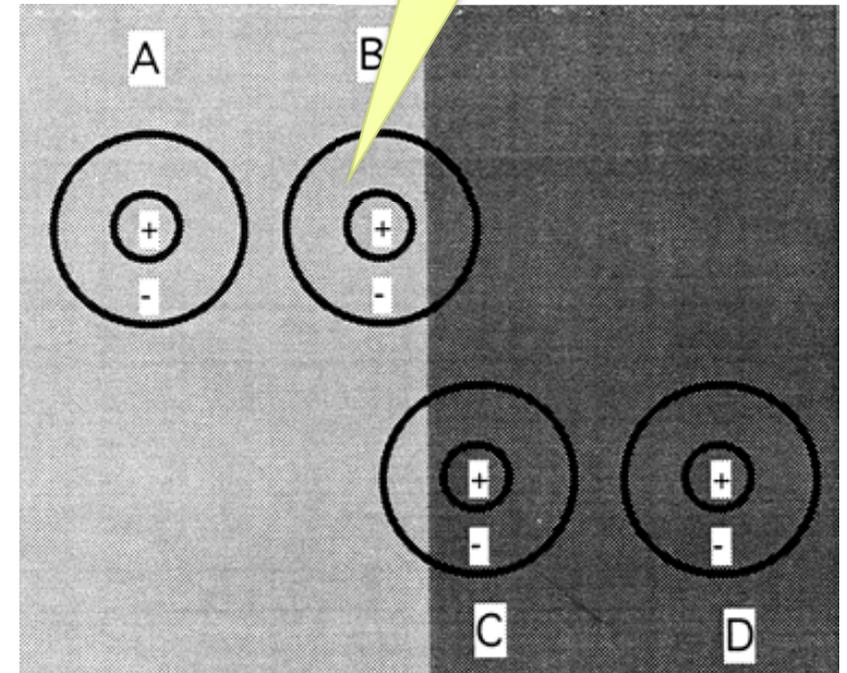

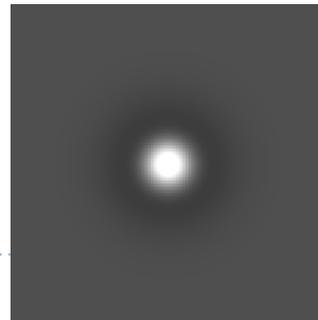

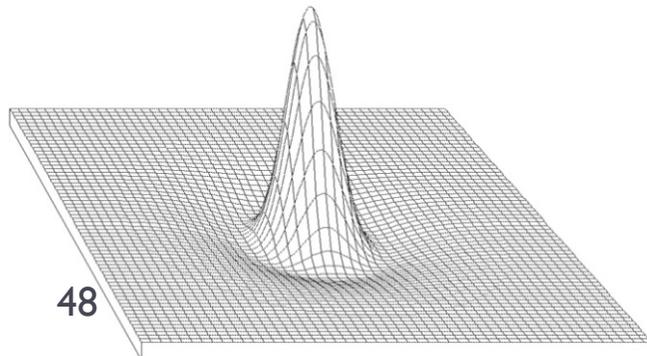

- “Overshooting” along edges
 - Extra-bright rims on bright sides
 - Extra-dark rims on dark sides
- Due to “Lateral Inhibition”

Centre-surround (Lateral Inhibition)

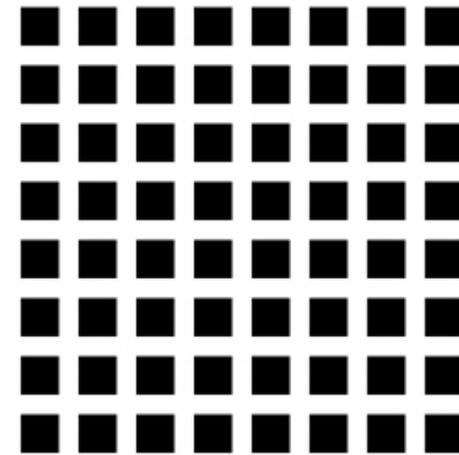

- ▶ “Pre-processing” step within the retina
 - ▶ Surrounding brightness level weighted negatively
 - ▶ A: high stimulus, maximal bright inhibition
 - ▶ B: high stimulus, reduced inhibition & stronger response
 - ▶ D: low stimulus, maximal inhibition
 - ▶ C: low stimulus, increased inhibition & weaker response

Center-surround receptive fields (groups of photoreceptors)

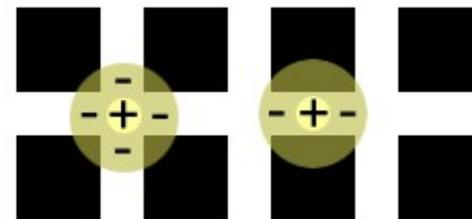

Centre-surround: Hermann Grid

- Dark dots at crossings
- Explanation
 - Crossings (A)
 - More surround stimulation (more bright area)
 - ⇒ Less inhibition
 - ⇒ Weaker response
 - Streets (B)
 - Less surround stimulation
 - ⇒ More inhibition
 - ⇒ Greater response
- Simulation
 - Darker at crossings, brighter in streets
 - Appears more steady
 - What if reversed ?

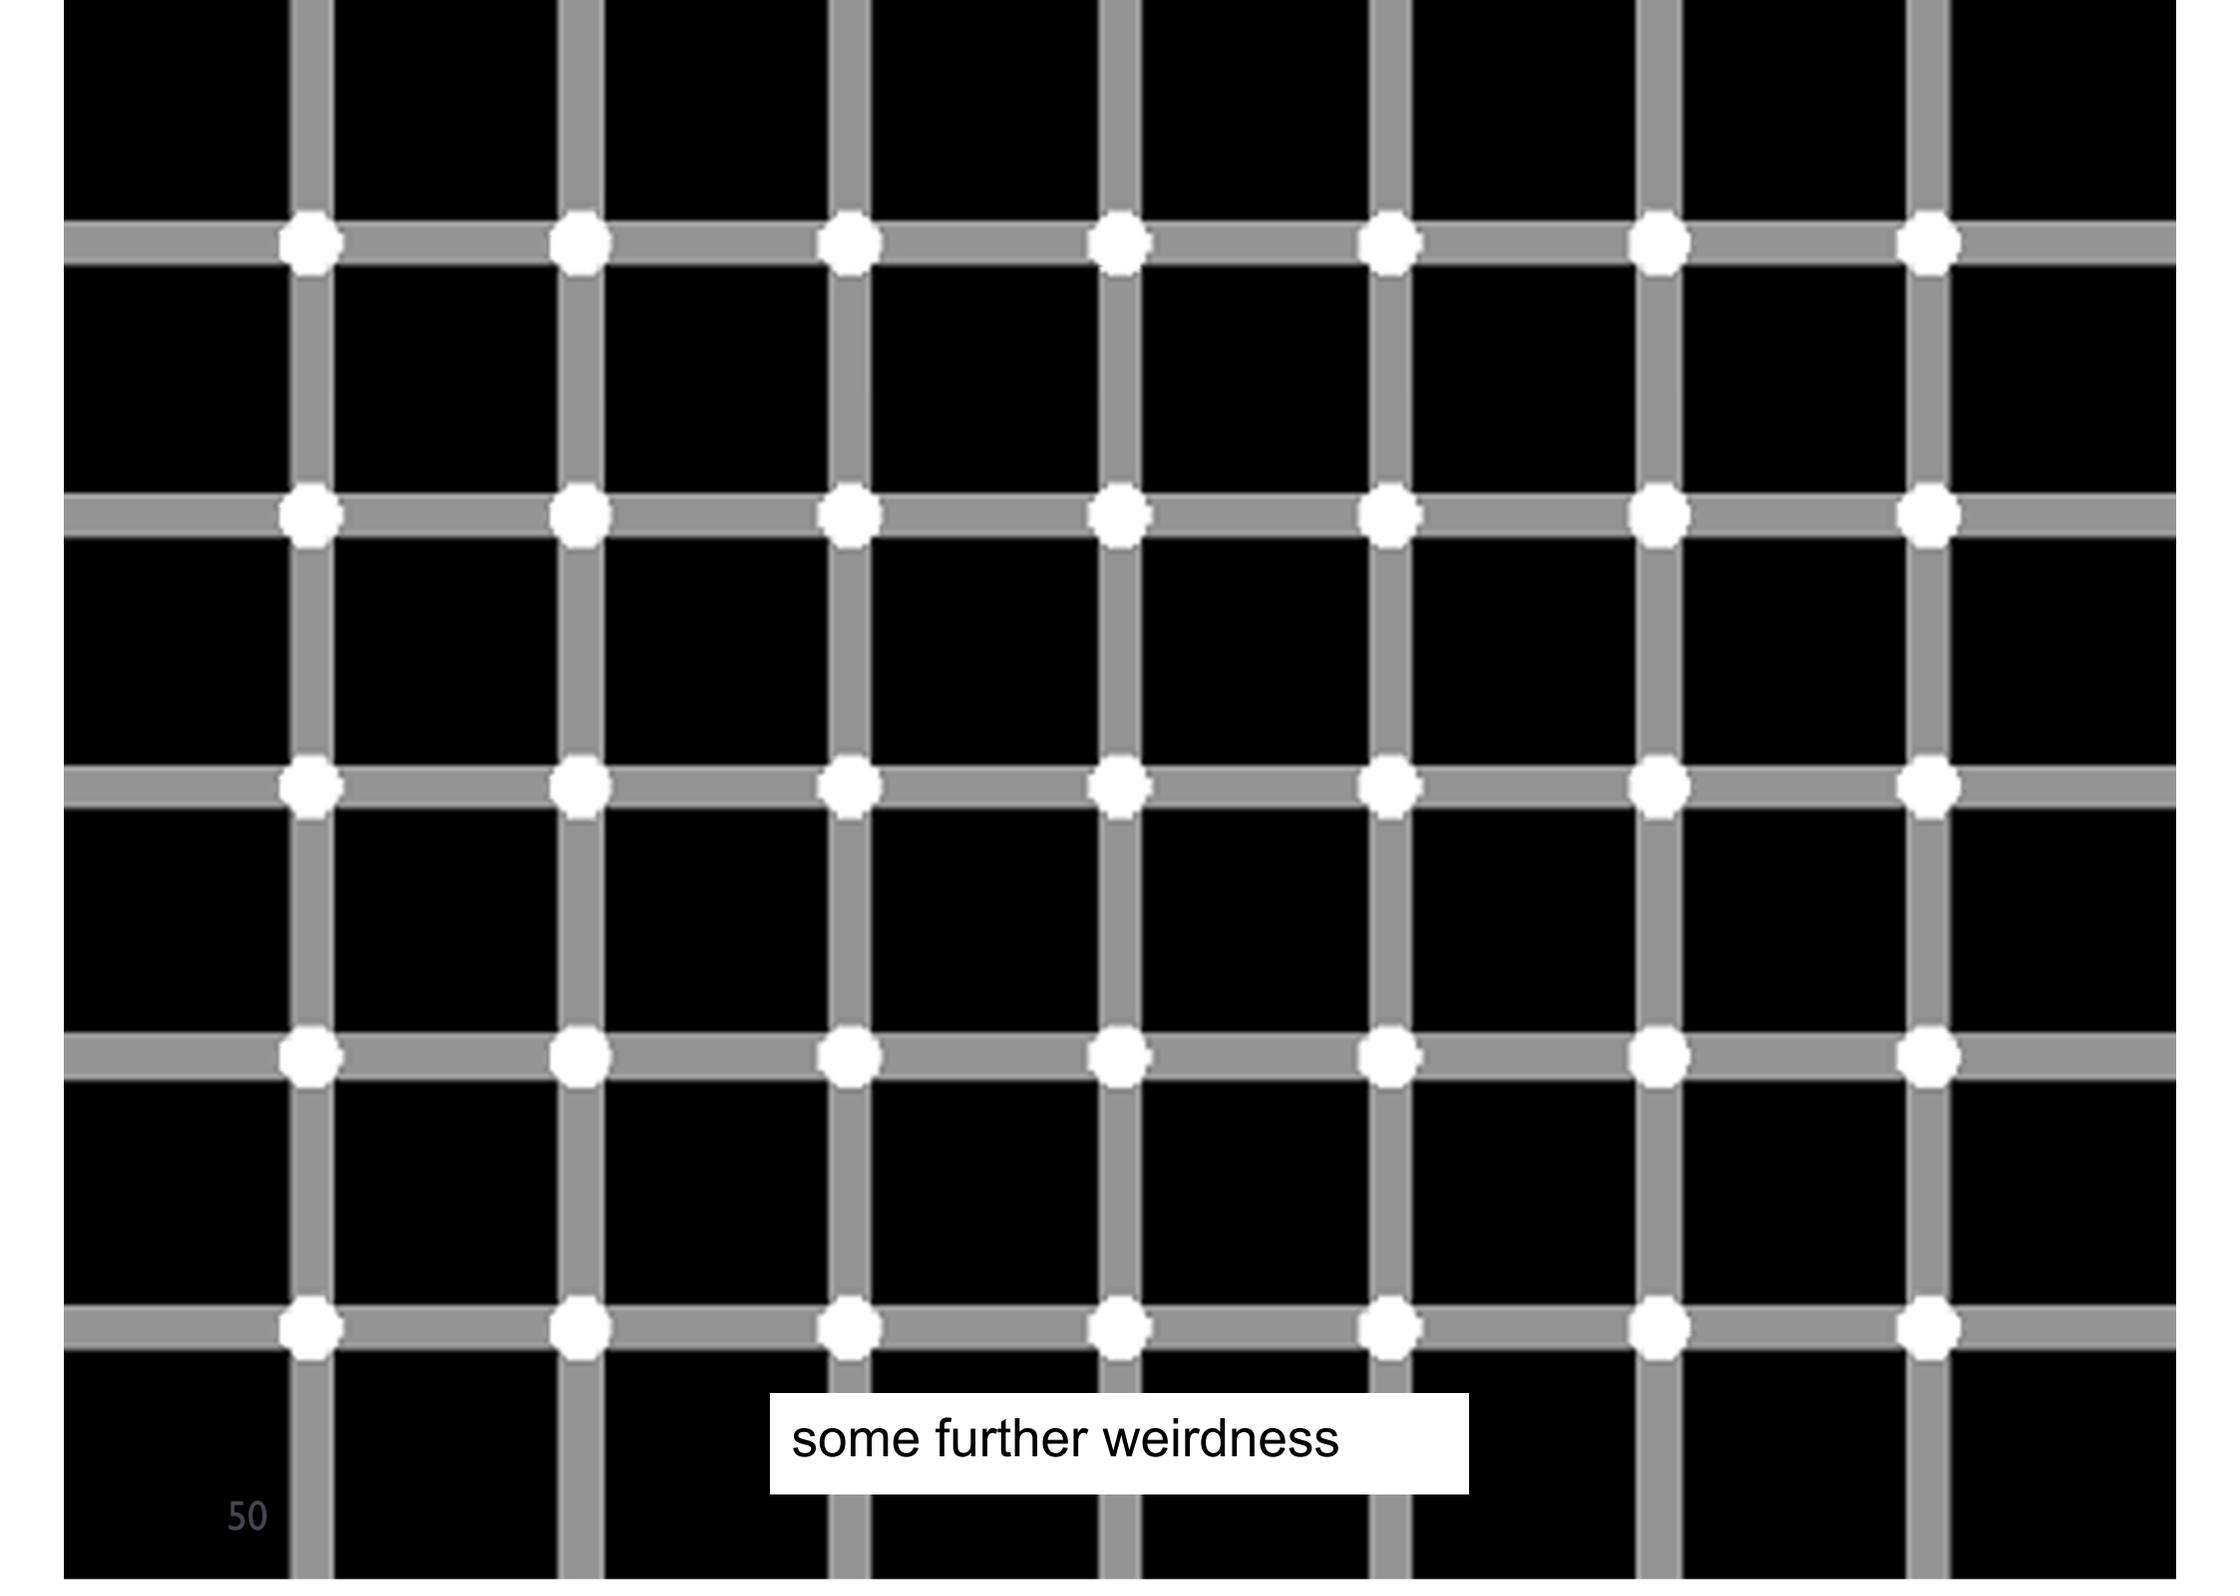

A

B

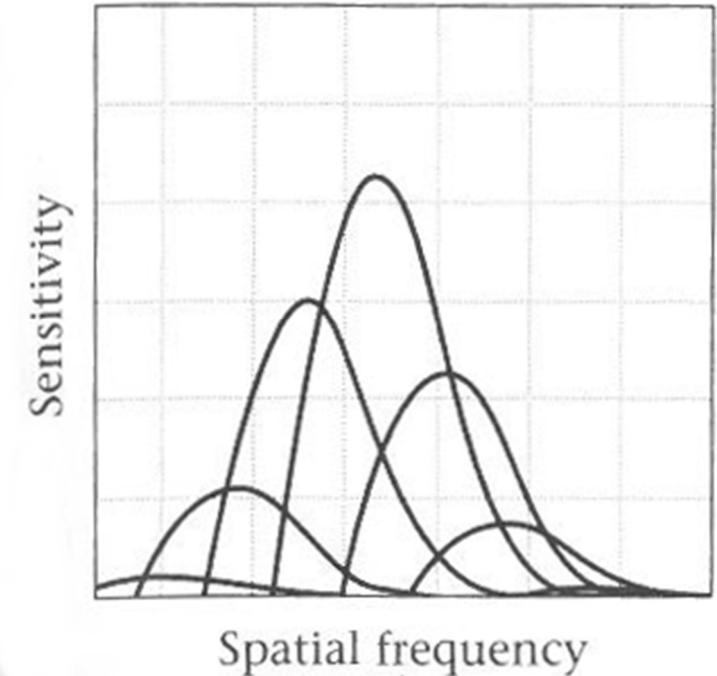

Simulation

some further weirdness

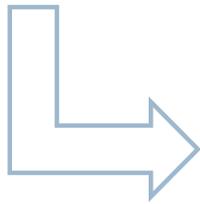

Spatial-frequency selective channels

- ▶ The visual information is decomposed in the visual cortex into multiple channels
 - ▶ The channels are selective to spatial frequency, temporal frequency and orientation
 - ▶ Each channel is affected by different „noise” level
 - ▶ The CSF is the net result of information being passed in noise-affected visual channels

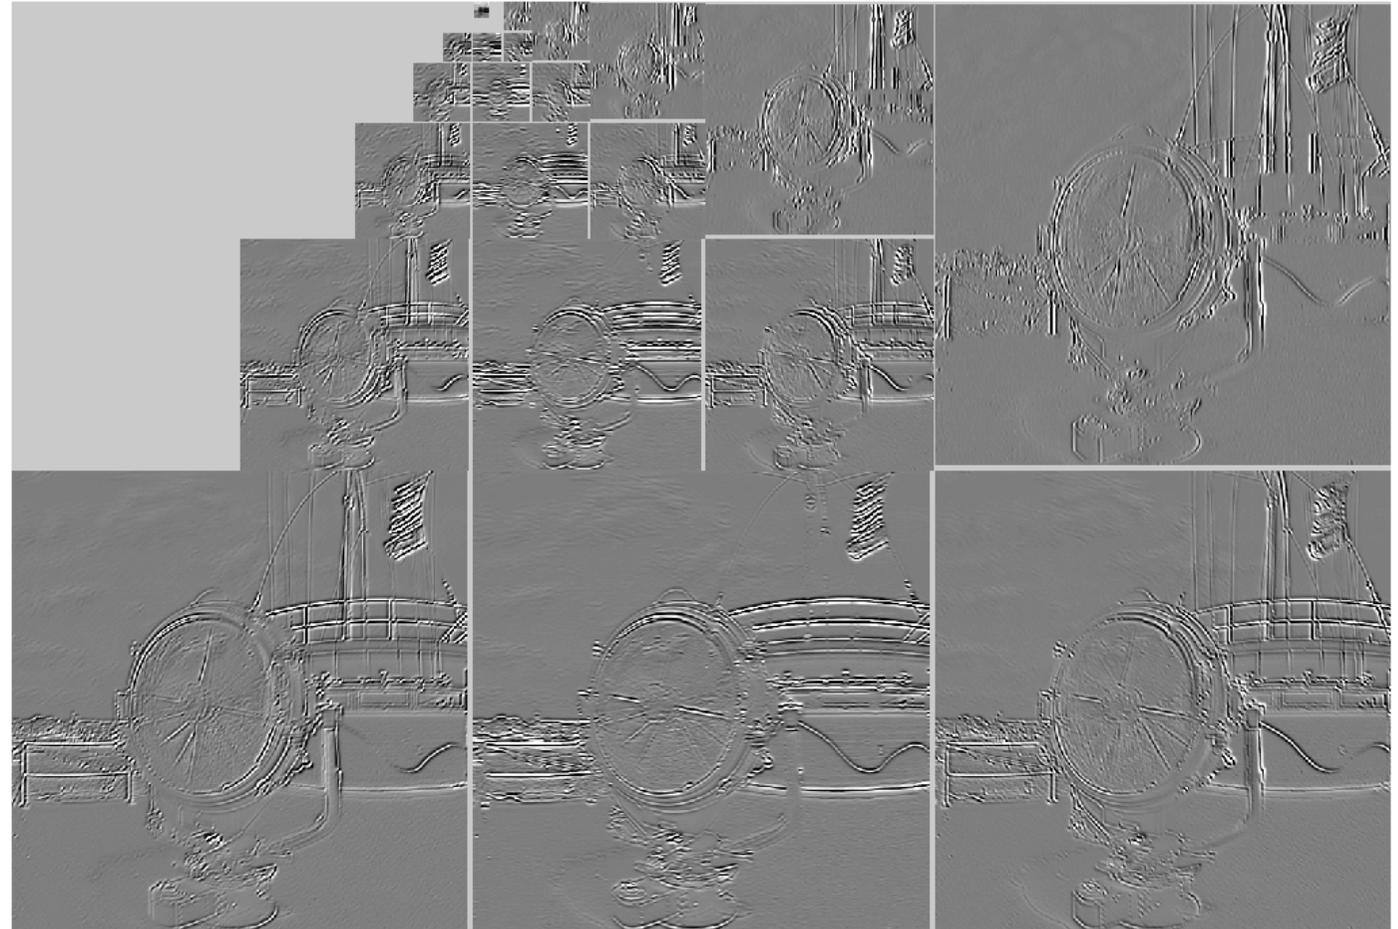

From: Wandell, 1995

Multi-scale decomposition

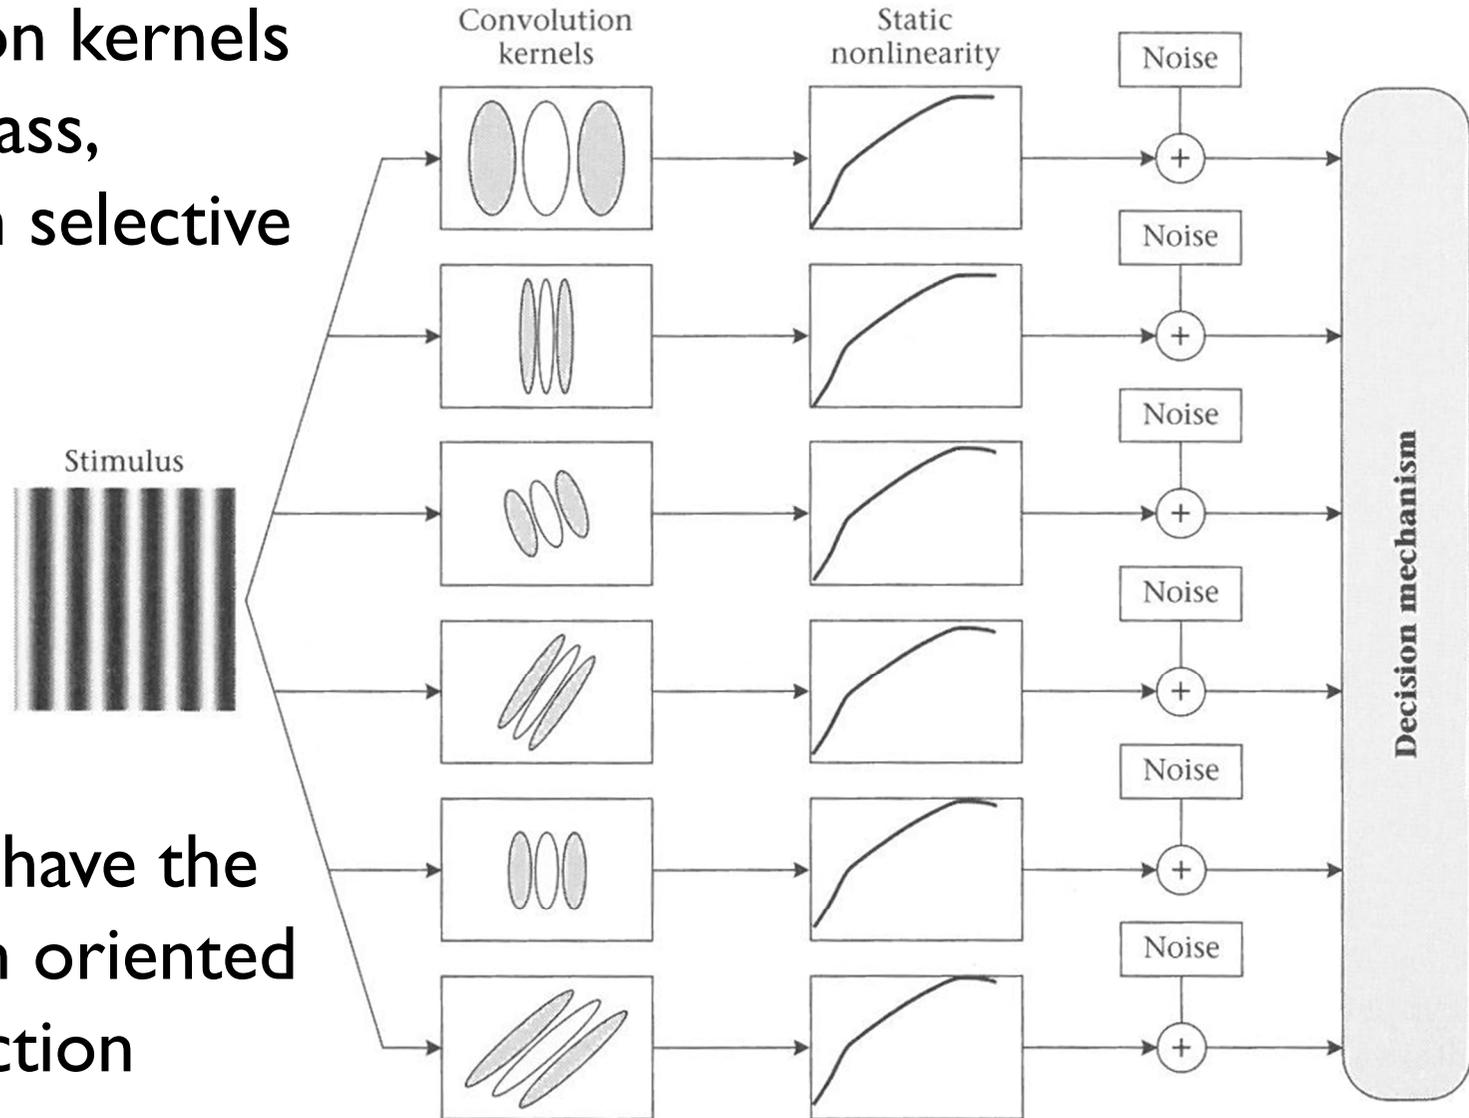

Steerable pyramid
decomposition

Multi-resolution visual model

- ▶ Convolution kernels are band-pass, orientation selective filters

- ▶ The filters have the shape of an oriented Gabor function

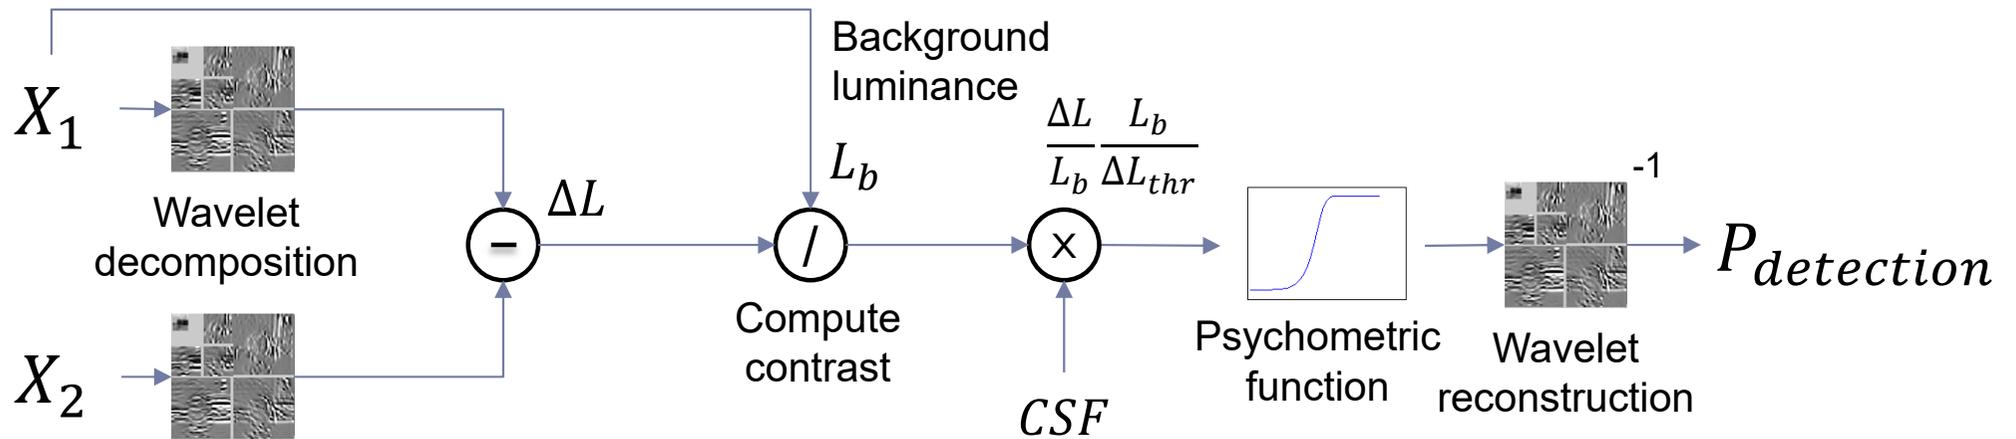

From: Wandell, 1995

Predicting visible differences with CSF

- ▶ We can use CSF to find the probability of spotting a difference between a pair of images X_1 and X_2 :

$$p(f[X_1] = f[X_2] | X_1, X_2, CSF)$$

$f[X]$ The percept of image X

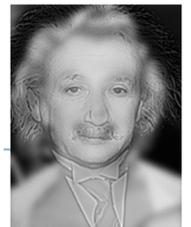

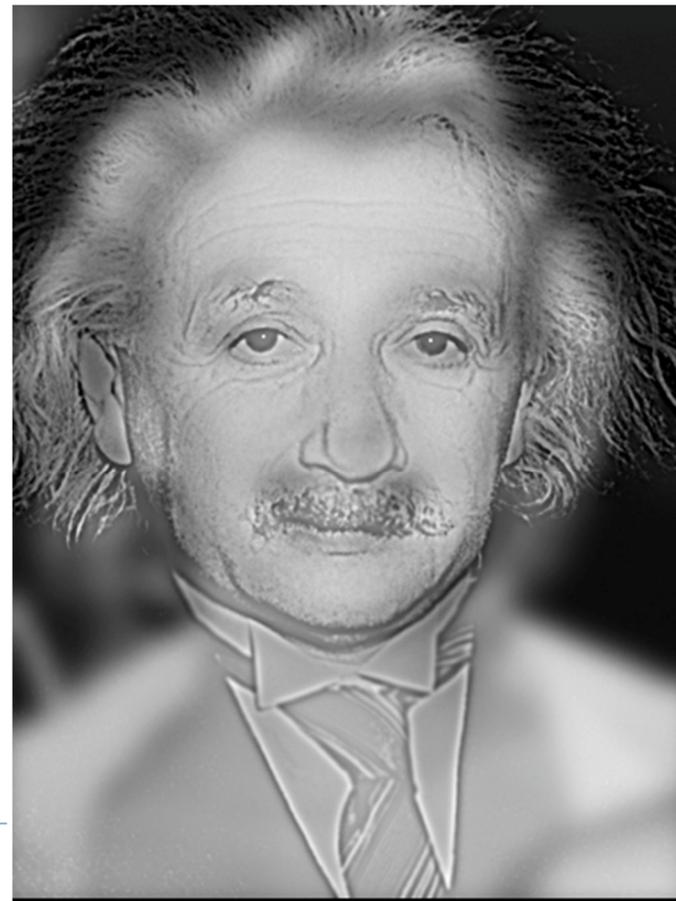

(simplified) Visual Difference Predictor

Daly, S. (1993).

Applications of multi-scale models

- ▶ **JPEG2000**
 - ▶ Wavelet decomposition
- ▶ **JPEG / MPEG**
 - ▶ Frequency transforms
- ▶ **Image pyramids**
 - ▶ Blending & stitching
 - ▶ Hybrid images

High dynamic range and tone mapping

Part 1/2 – context, the need for tone-mapping

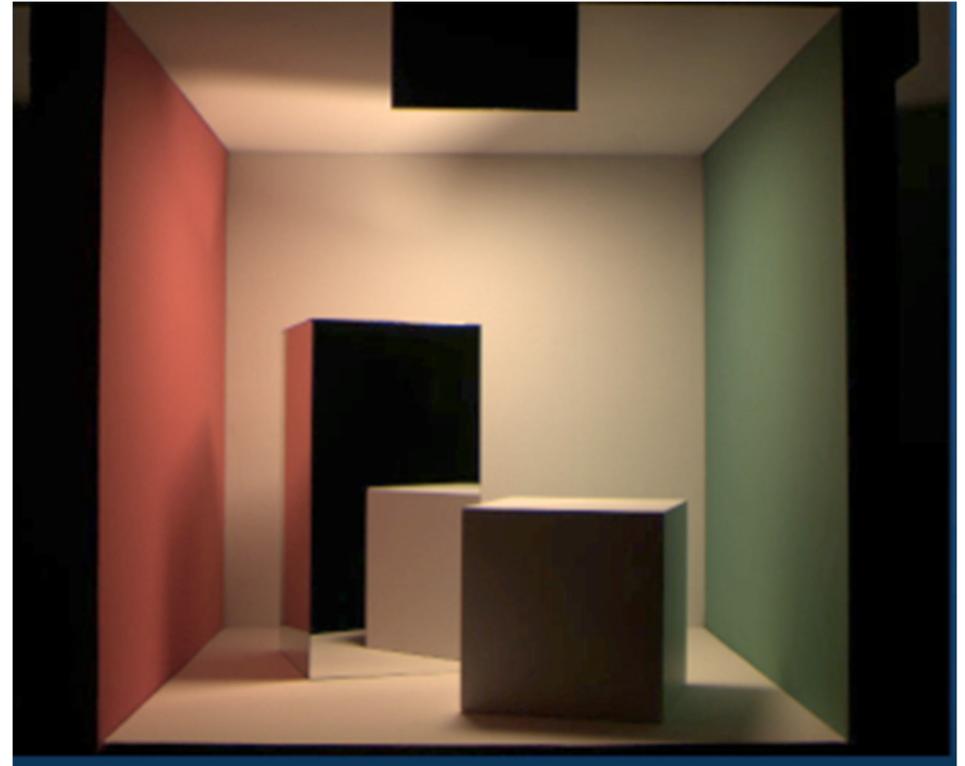

Rafał Mantiuk

Computer Laboratory, University of Cambridge

Cornell Box: need for tone-mapping in graphics

Rendering

Photograph

Real-world scenes are more challenging

- ▶ The match could not be achieved if the light source in the top of the box was visible
- ▶ The display could not reproduce the right level of brightness

Dynamic range

Luminance
↓
 $\frac{\max L}{\min L}$
↑
(for SNR>3)

Dynamic range (contrast)

- ▶ As ratio:

$$C = \frac{L_{\max}}{L_{\min}}$$

- ▶ Usually written as C:1, for example 1000:1.

- ▶ As “orders of magnitude”
or log10 units:

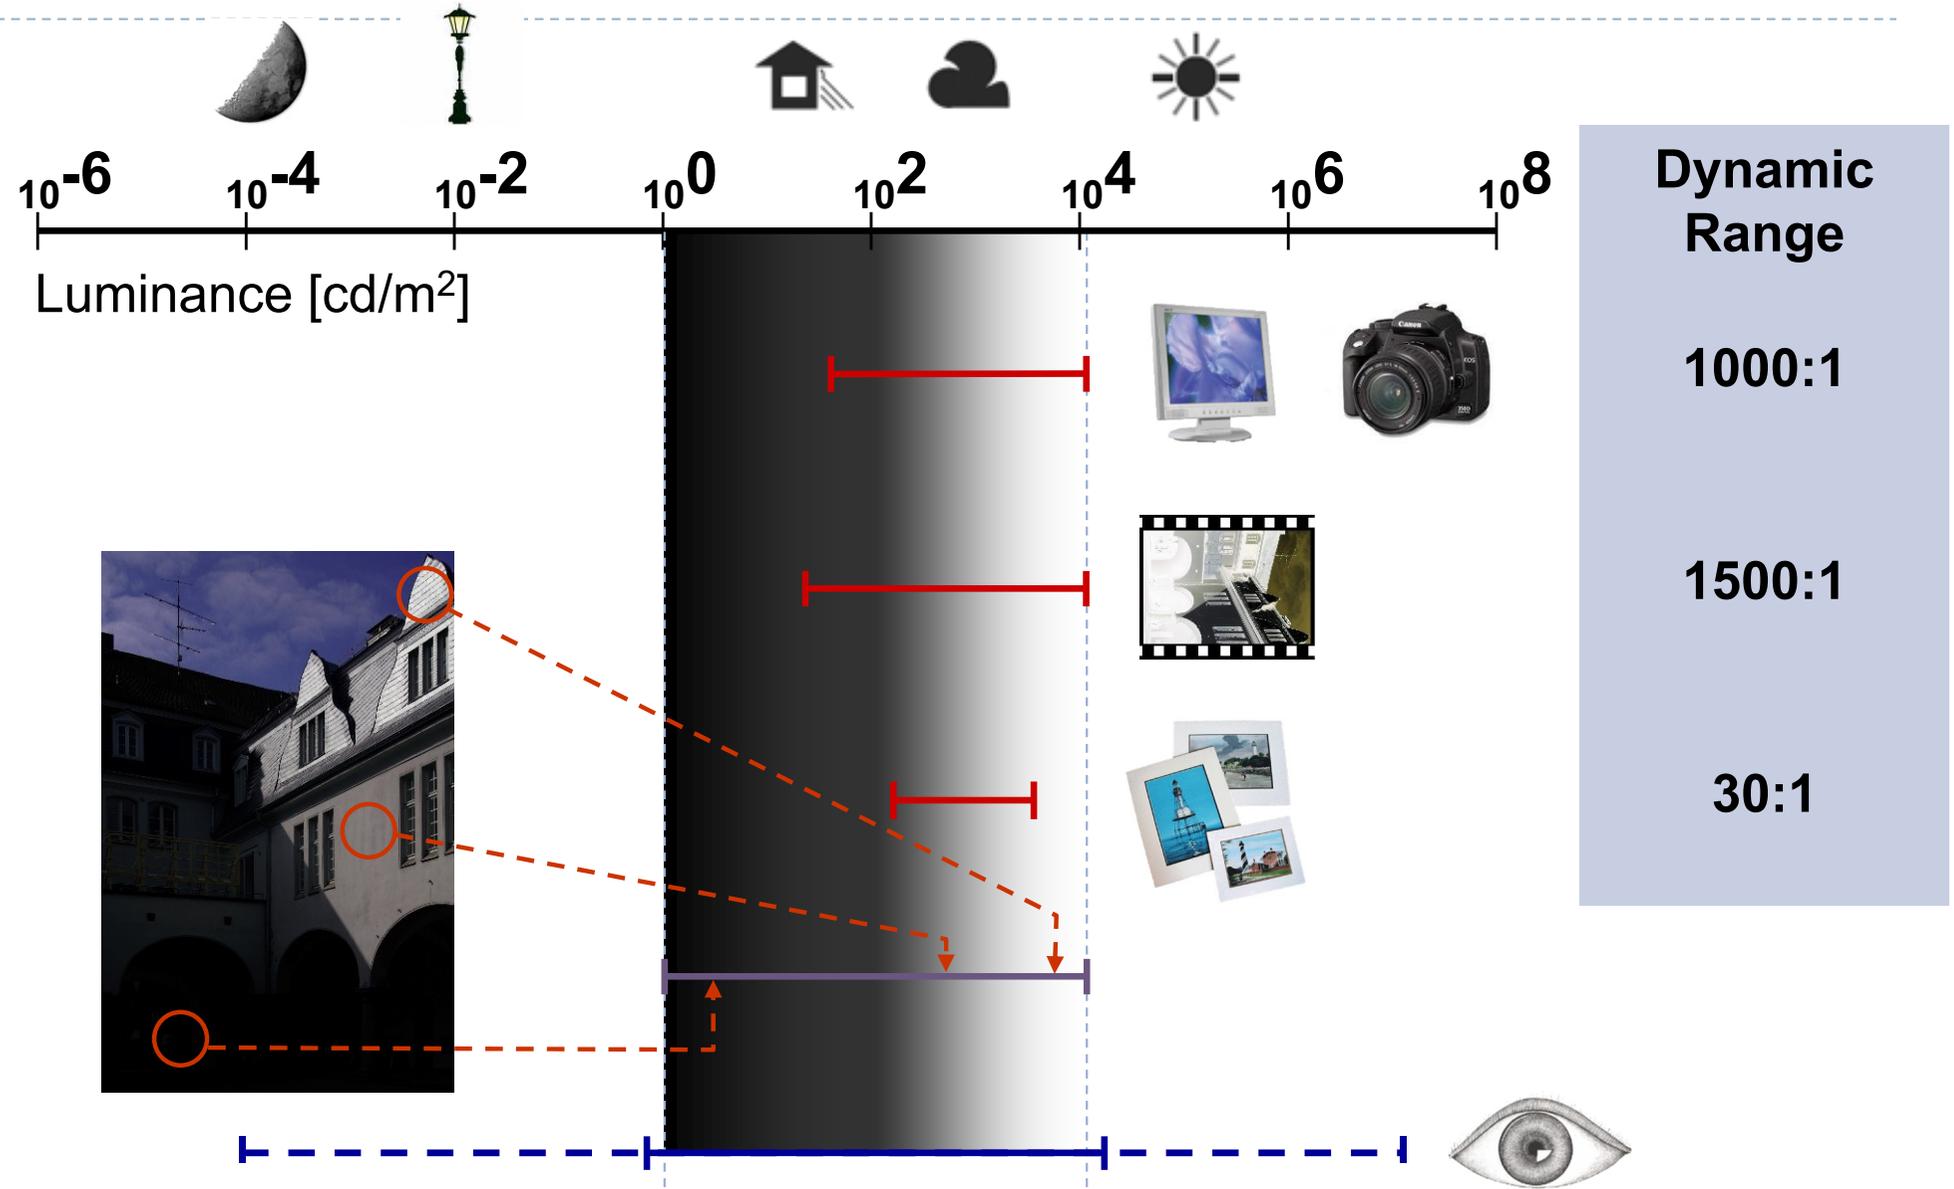

$$C_{10} = \log_{10} \frac{L_{\max}}{L_{\min}}$$

- ▶ As stops:

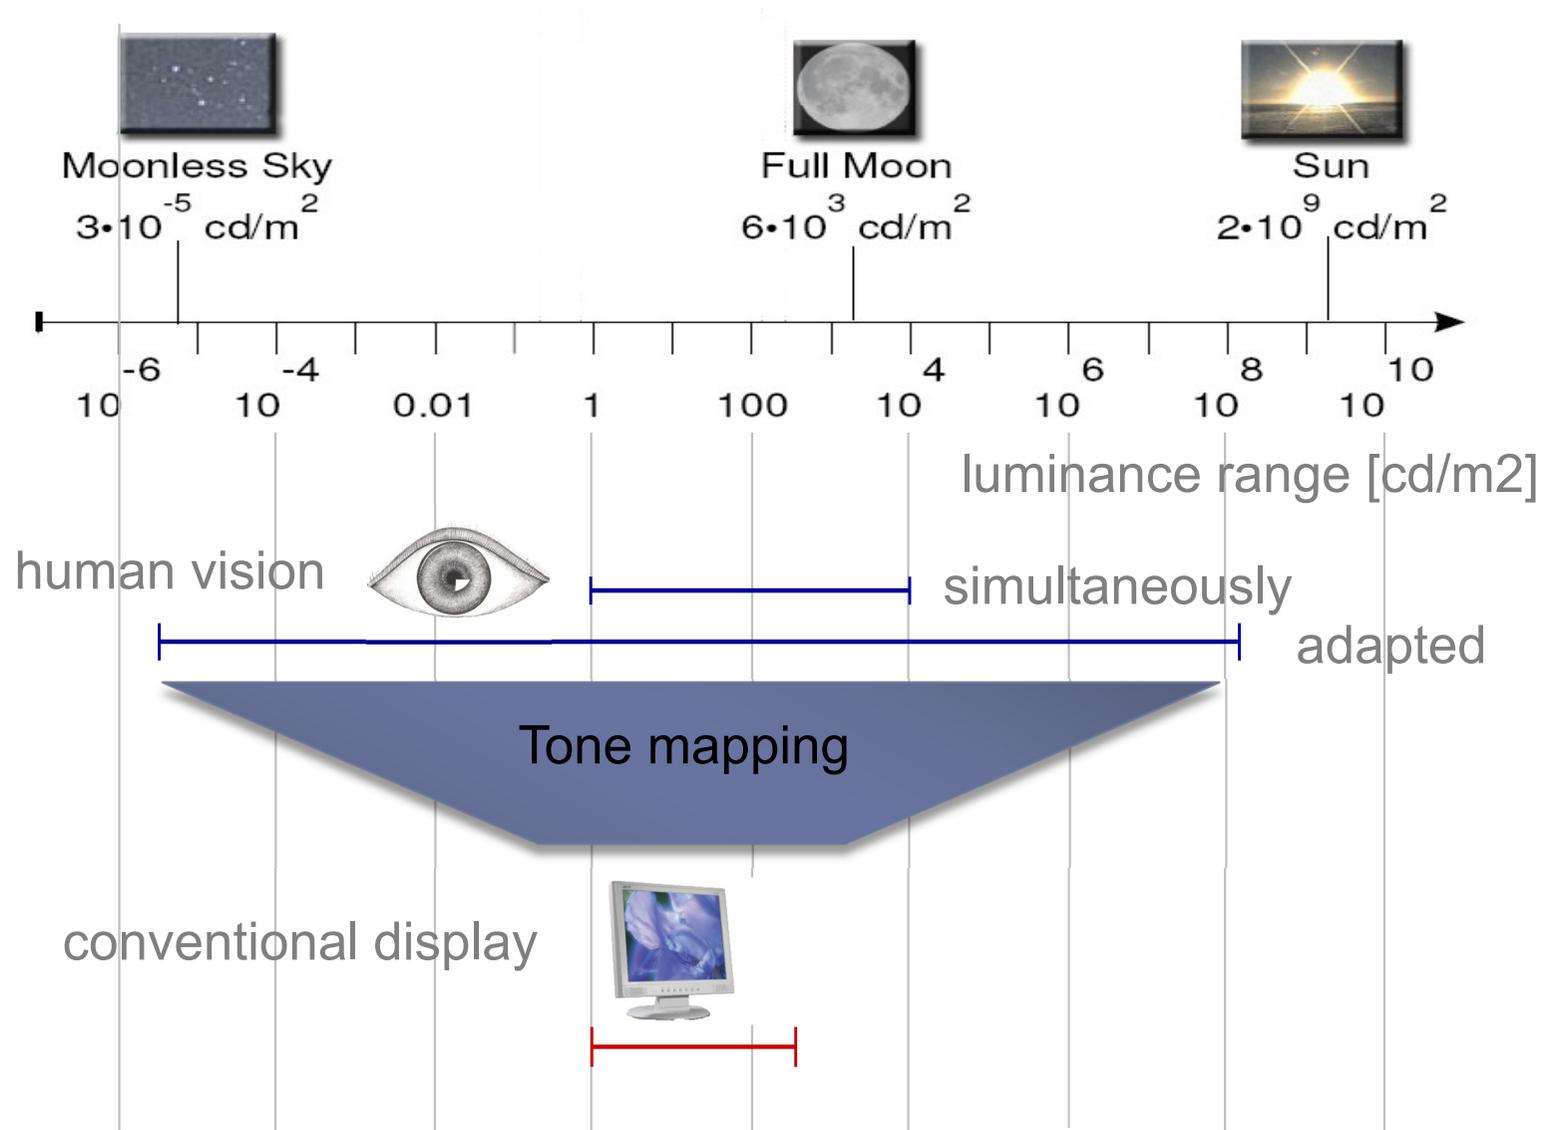

$$C_2 = \log_2 \frac{L_{\max}}{L_{\min}}$$

One stop is doubling
of halving the amount of light

High dynamic range (HDR)

Tone-mapping problem

Why do we need tone mapping?

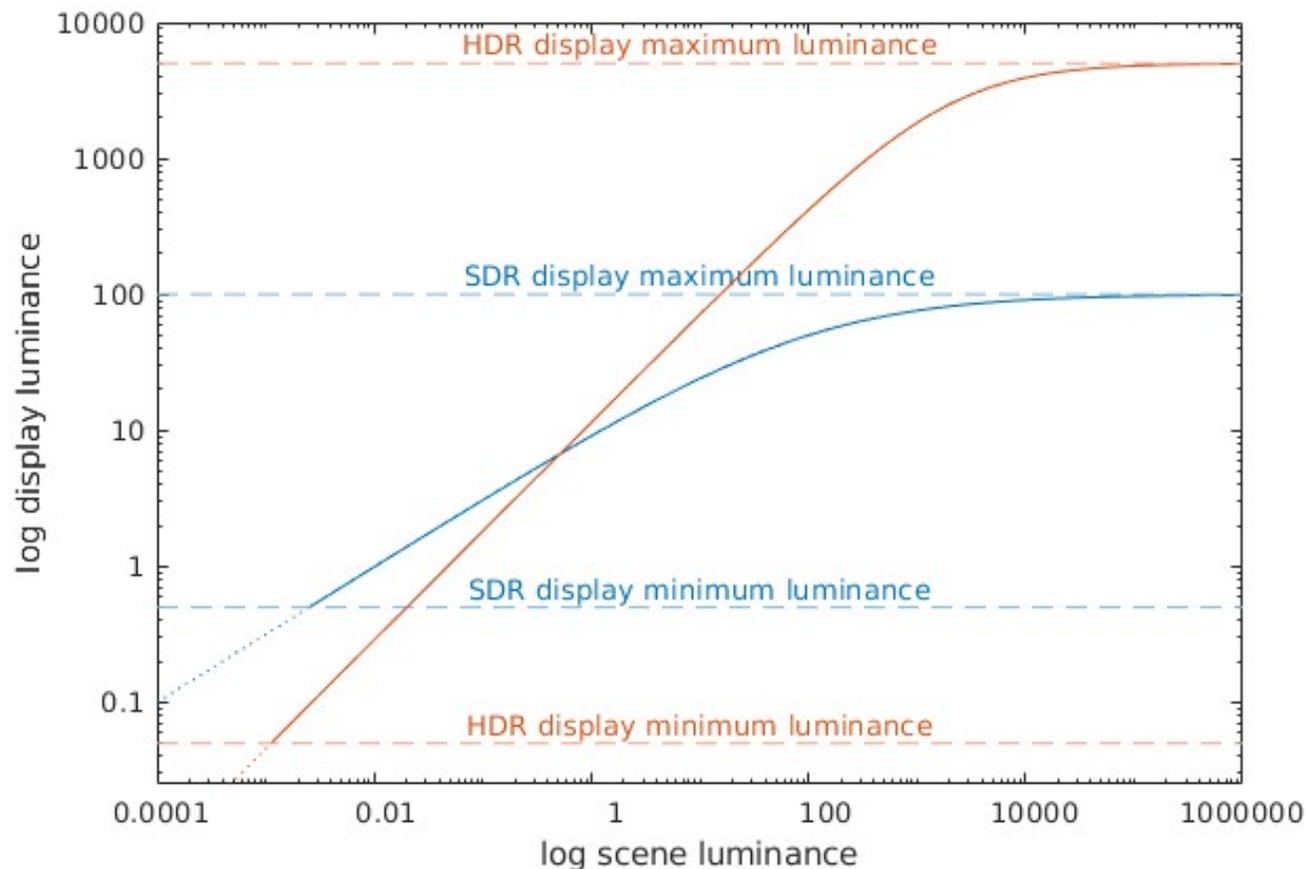

- ▶ To **reduce dynamic range**
- ▶ To **customize the look**
 - ▶ colour grading
- ▶ To **simulate human vision**
 - ▶ for example night vision
- ▶ To adapt displayed images to a **display and viewing conditions**
- ▶ To make rendered images look **more realistic**
- ▶ To map from **scene- to display-referred** colours

- ▶ Different tone mapping operators achieve different goals

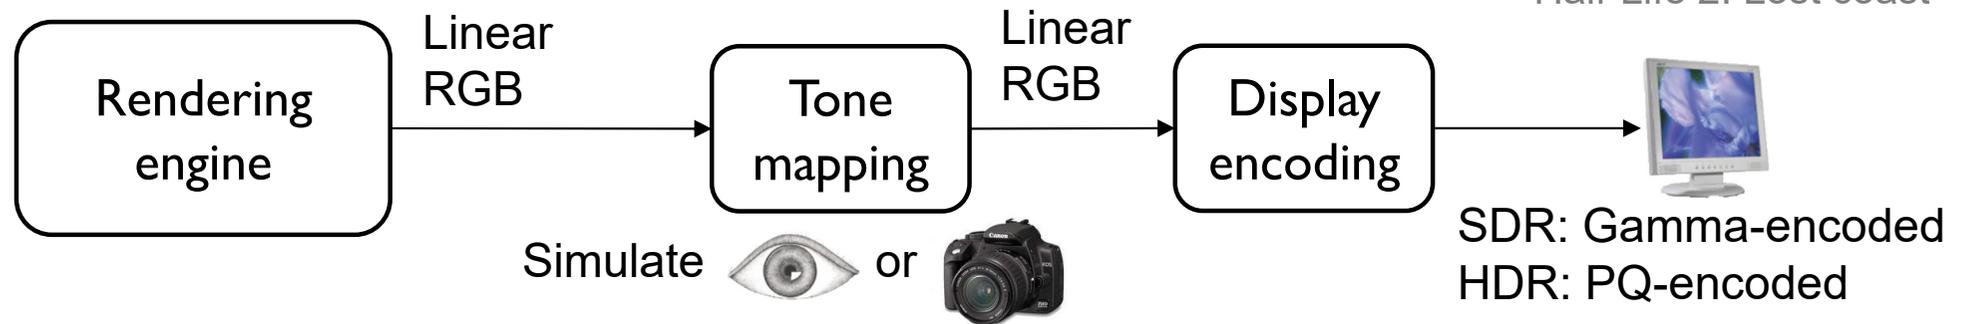

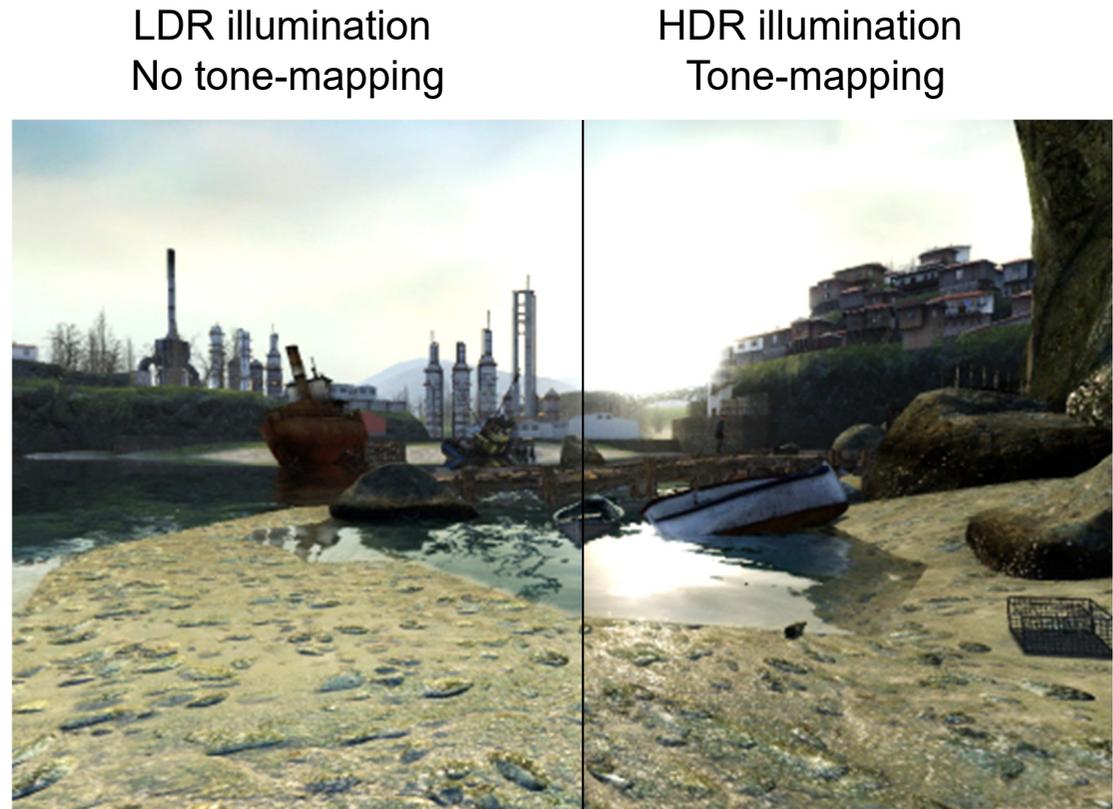

From scene- to display-referred colours

- ▶ The primary purpose of tone mapping is to transform an image from *scene-referred* to *display-referred* colours

Tone-mapping in rendering

- ▶ Any physically-based rendering requires tone-mapping
- ▶ “HDR rendering” in games is pseudo-physically-based rendering
- ▶ Goal: to simulate a camera or the eye
- ▶ Greatly enhances realism

Basic tone-mapping and display coding

- ▶ The simplest form of tone-mapping is the exposure/brightness adjustment:

$$R_d = \frac{R_s}{L_{white}}$$

Display-referred red value

Scene-referred

Scene-referred luminance of white

- ▶ R for red, the same for green and blue
- ▶ No contrast compression, only for a moderate dynamic range
- ▶ The simplest form of display coding is the “gamma”

$$R' = (R_d)^{\frac{1}{\gamma}}$$

Prime (') denotes a gamma-corrected value

Typically $\gamma=2.2$

- ▶ For SDR displays only

UNIVERSITY OF
CAMBRIDGE
COMPUTER LABORATORY

Advanced Graphics and Image Processing

High dynamic range and tone mapping

Part 2/2 – tone mapping techniques

Rafał Mantiuk

Computer Laboratory, University of Cambridge

Techniques

- ▶ Arithmetic of HDR images
- ▶ Display model
- ▶ Tone-curve
- ▶ Colour transfer
- ▶ Base-detail separation
- ▶ Glare

Arithmetic of HDR images

- ▶ How do the basic arithmetic operations
 - ▶ Addition
 - ▶ Multiplication
 - ▶ Power function

affect the appearance of an HDR image?

- ▶ We work in the luminance space (NOT luma)
- ▶ The same operations can be applied to linear RGB
 - ▶ Or only to luminance and the colour can be transferred

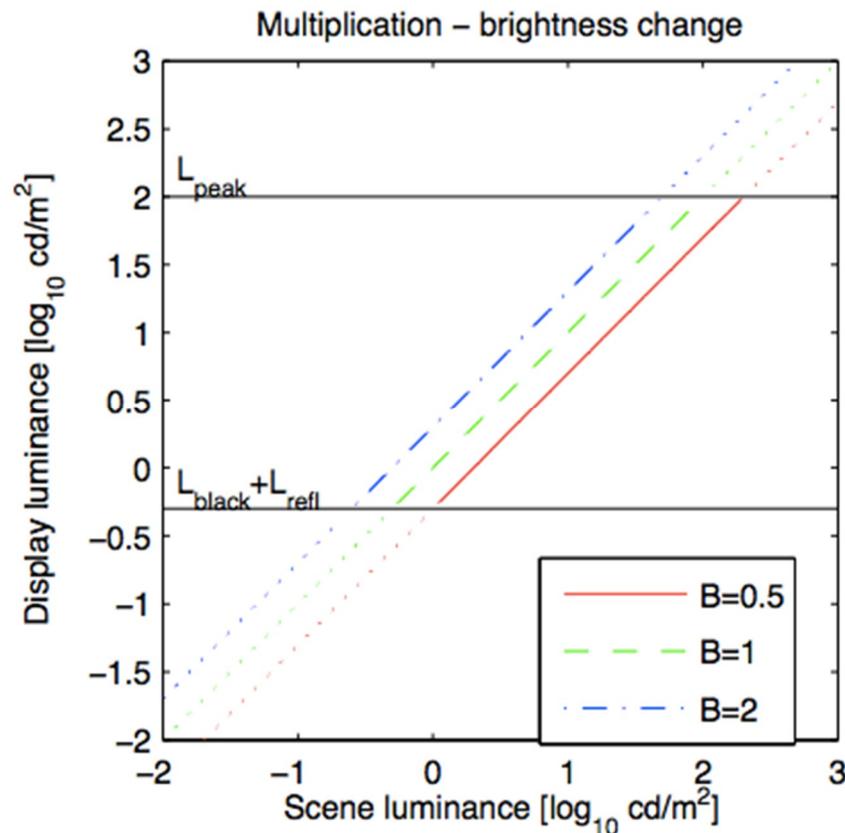

Multiplication – brightness change

Resulting
luminance

Input
luminance

$$T(L_p) = B \cdot L_p$$

Brightness change
parameter

- ▶ Multiplication makes the image brighter or darker
- ▶ It does not change the dynamic range!

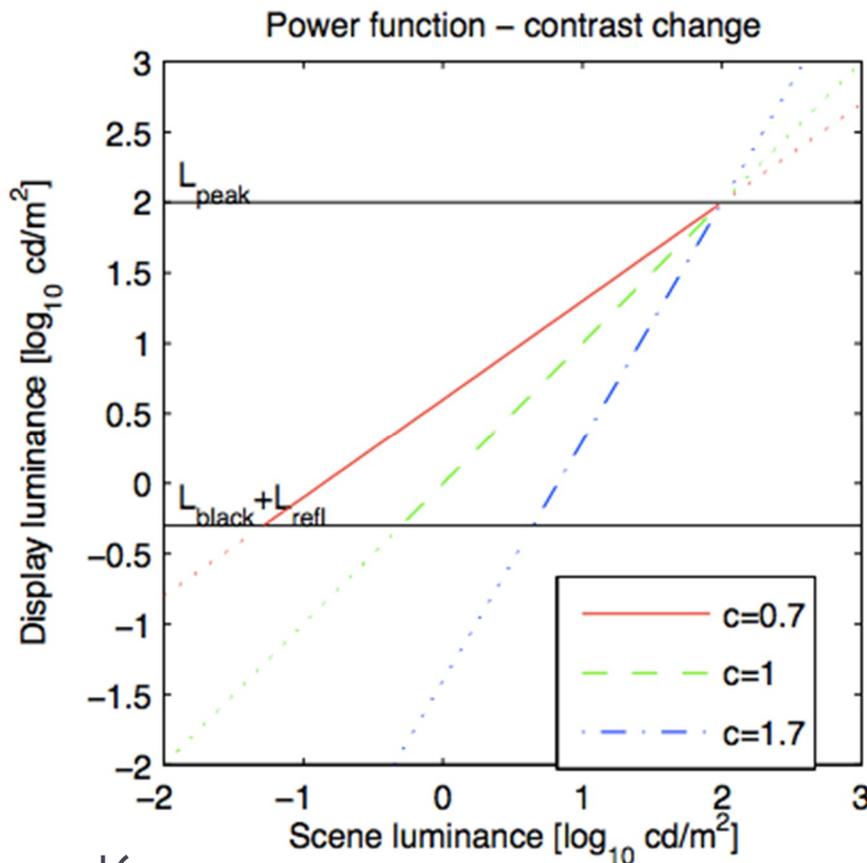

Power function – contrast change

$$T(L_p) = \left(\frac{L_p}{L_{white}} \right)^c$$

Contrast change
(gamma)

Luminance of
white

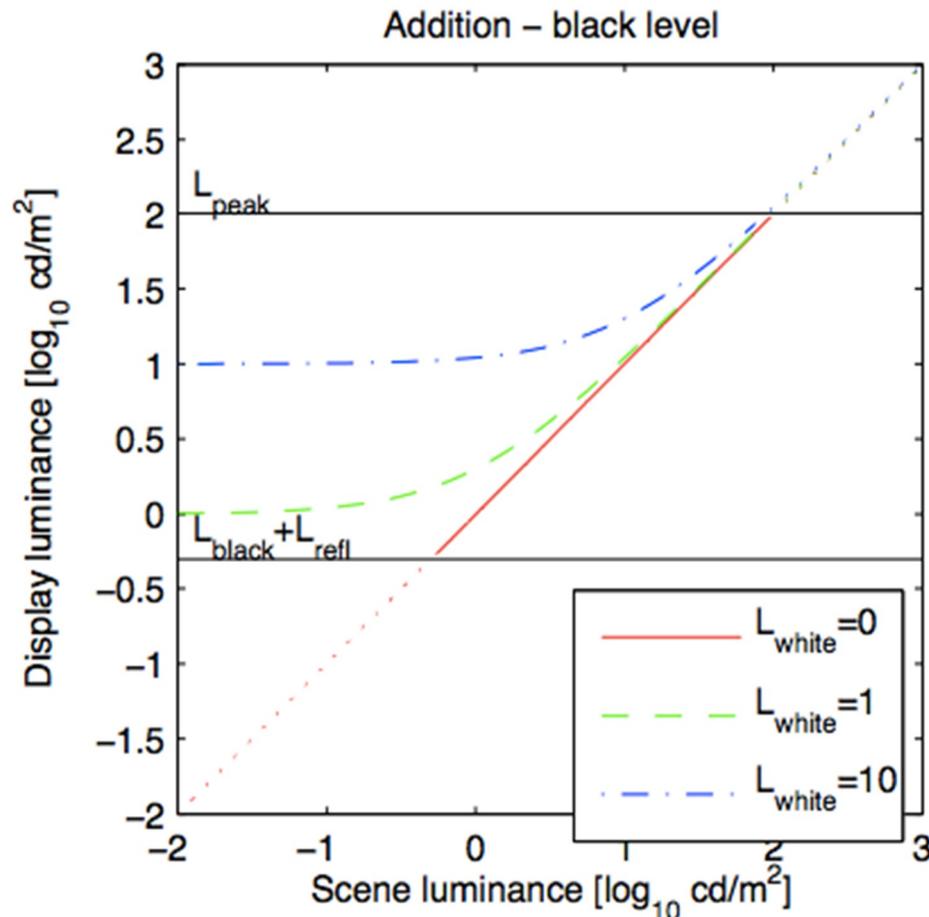

- ▶ Power function stretches or shrinks the dynamic range of an image
- ▶ It is usually performed relative to a reference white colour (and luminance)
- ▶ Side effect: brightness of the dark image part will change
- ▶ Slope on a log-log plot explains contrast change

Addition – black level

$$T(L_p) = L_p + F$$

Black level
(flare, fog)

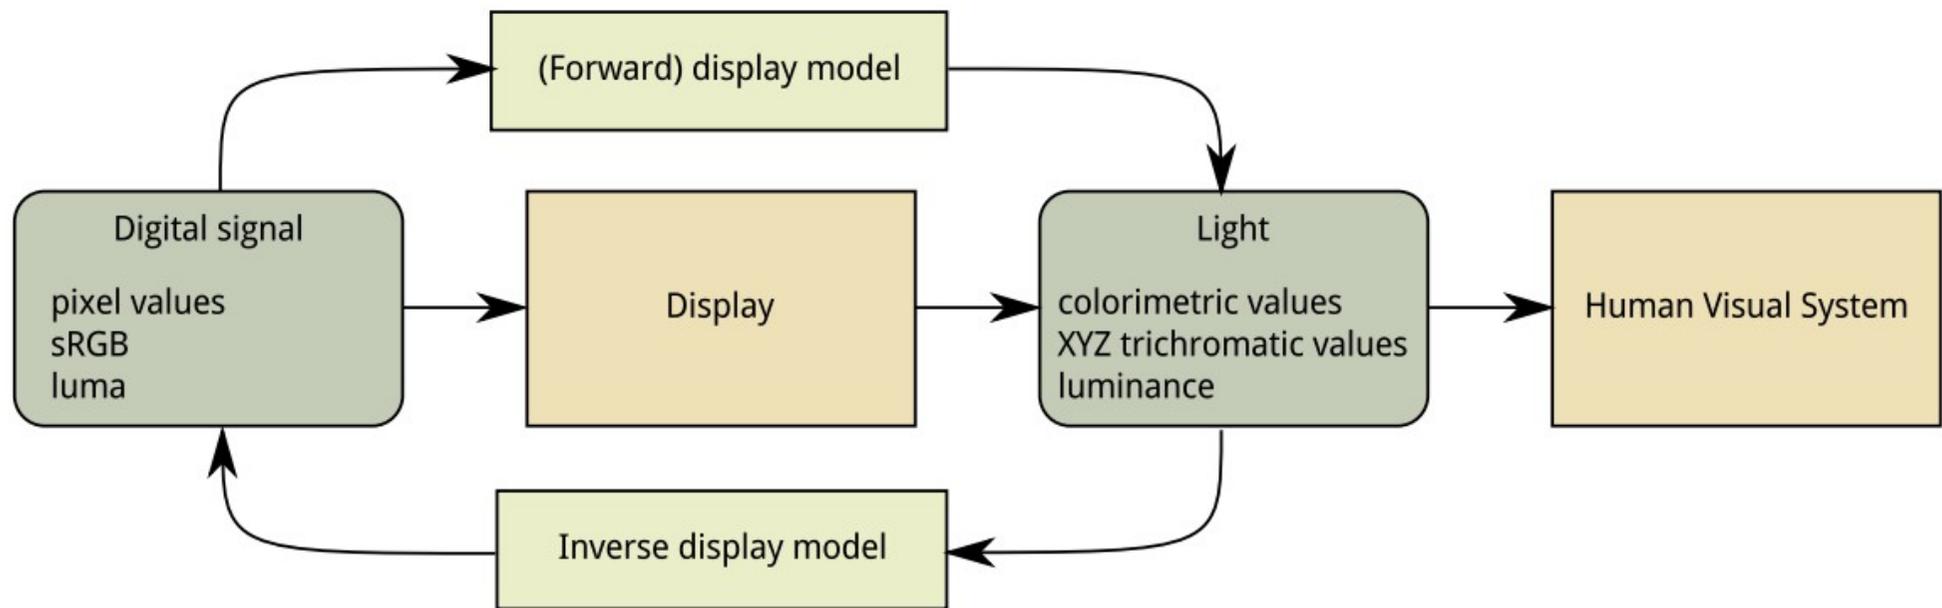

- ▶ Addition elevates black level, adds „fog” to an image
- ▶ It affects mostly darker tones
- ▶ It reduces image dynamic range
- ▶ Subtraction can compensate for ambient light (shown next)

Techniques

- ▶ Arithmetic of HDR images
- ▶ **Display model**
- ▶ Tone-curve
- ▶ Colour transfer
- ▶ Base-detail separation
- ▶ Glare

Display-adaptive tone mapping

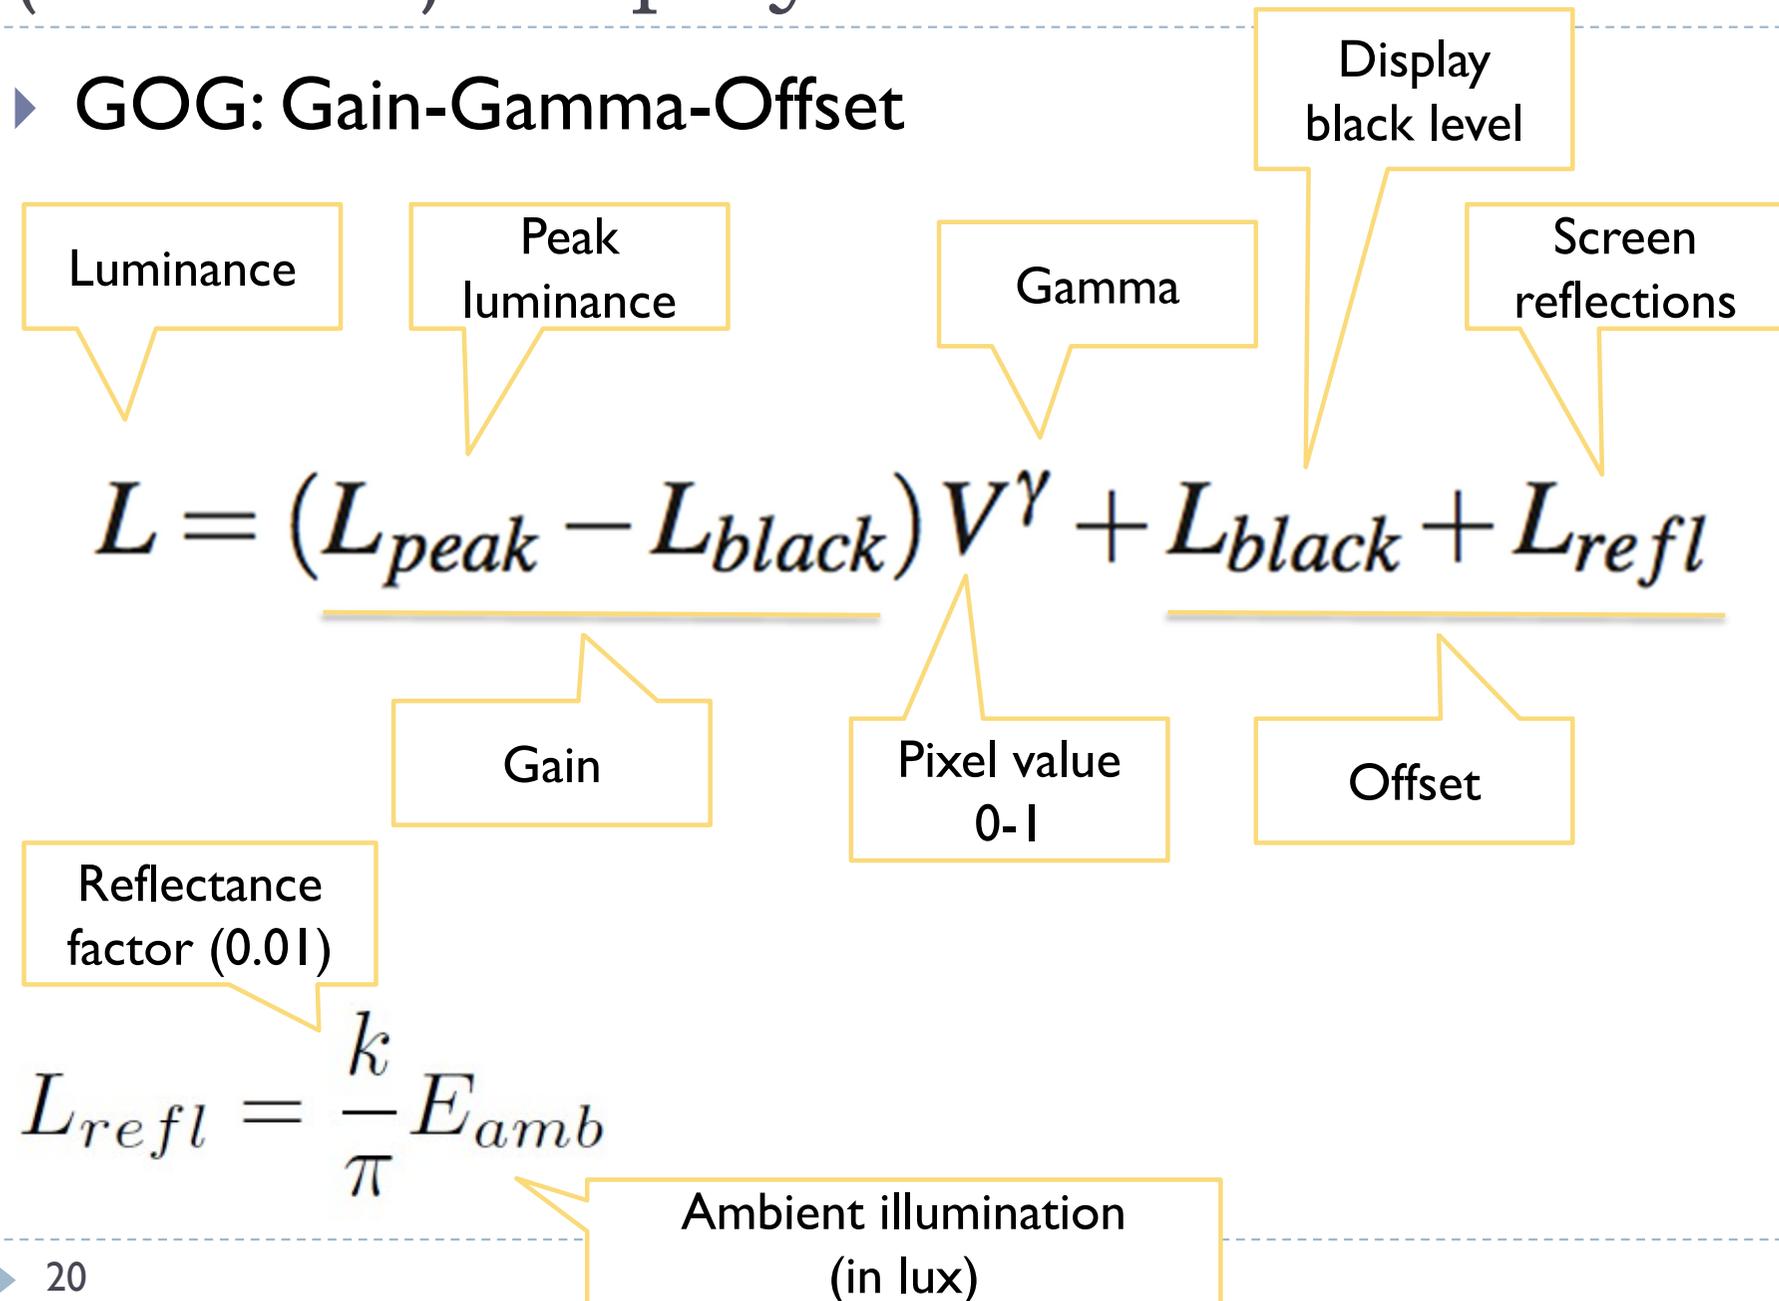

- ▶ Tone-mapping can account for the physical model of a display
 - ▶ How a display transforms pixel values into emitted light
 - ▶ Useful for ambient light compensation

Has a similar role as display encoding, but can account for viewing conditions

(Forward) Display model

► GOG: Gain-Gamma-Offset

Inverse display model

Symbols are the same as for the forward display model

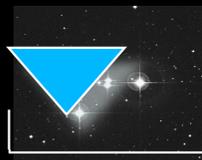

$$V = \left(\frac{L - L_{black} - L_{refl}}{L_{peak} - L_{black}} \right)^{(1/\gamma)}$$

Note: This display model does not address any colour issues. The same equation is applied to red, green and blue color channels. The assumption is that the display primaries are the same as for the sRGB color space.

Ambient illumination compensation

Non-adaptive TMO

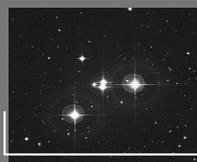

Display adaptive TMO

Ambient illumination compensation

Non-adaptive TMO

Display adaptive TMO

10^{23}

300

10 000

lux

Example: Ambient light compensation

- ▶ We are looking at the screen in bright light

$$L_{peak} = 100 [cd \cdot m^{-2}]$$

$$k = 0.005$$

Modern screens have reflectivity of around 0.5%

$$L_{black} = 0.1 [cd \cdot m^{-2}]$$

$$E_{amb} = 2000 [lux] \quad L_{refl} = \frac{0.005}{\pi} 2000 = 3.183 [cd \cdot m^{-2}]$$

- ▶ We assume that the dynamic of the input is 2.6 ($\approx 400:1$)

$$r_{in} = 2.6 \quad r_{out} = \log_{10} \frac{L_{peak}}{L_{black} + L_{refl}} = 1.77$$

- ▶ First, we need to compress contrast to fit the available dynamic range, then compensate for ambient light

$$L_{out} = \left(\frac{L_{in}}{L_{wp}} \right)^{\frac{r_{out}}{r_{in}}} - L_{refl}$$

The resulting value is in luminance, must be mapped to display luma / gamma corrected values (display encoded)

Simplest, but not the best tone mapping

Techniques

- ▶ Arithmetic of HDR images
- ▶ Display model
- ▶ **Tone-curve**
- ▶ Colour transfer
- ▶ Base-detail separation
- ▶ Glare

Tone-curve

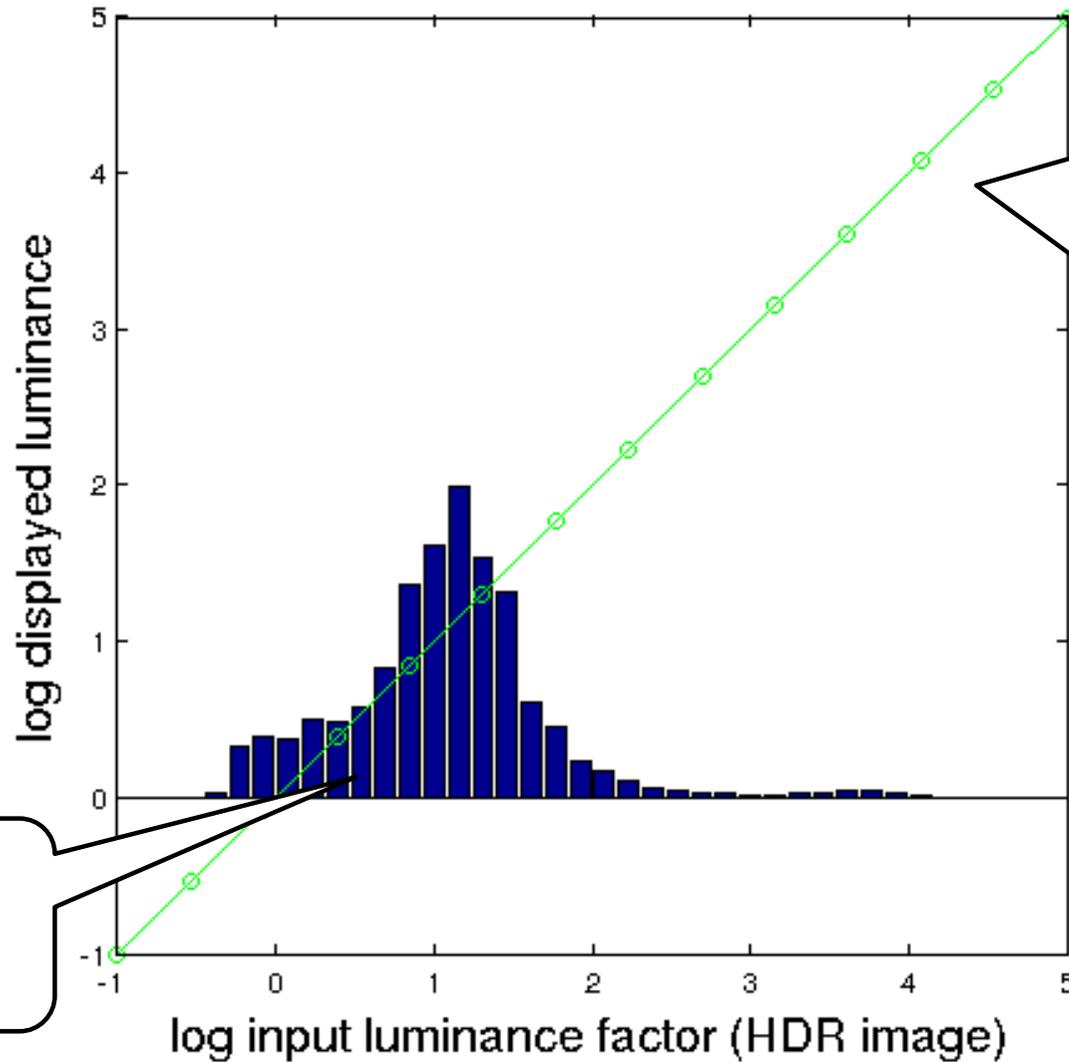

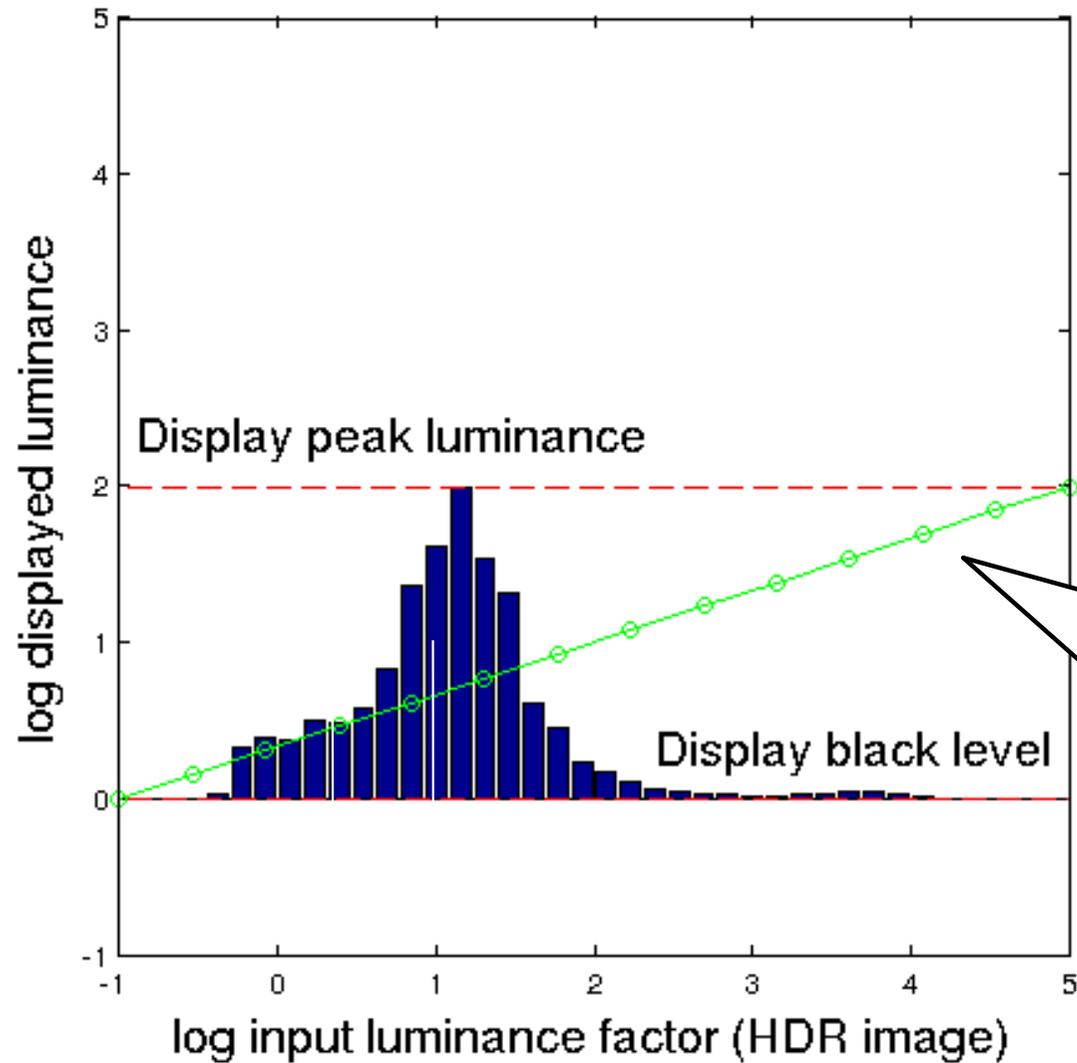

Image histogram

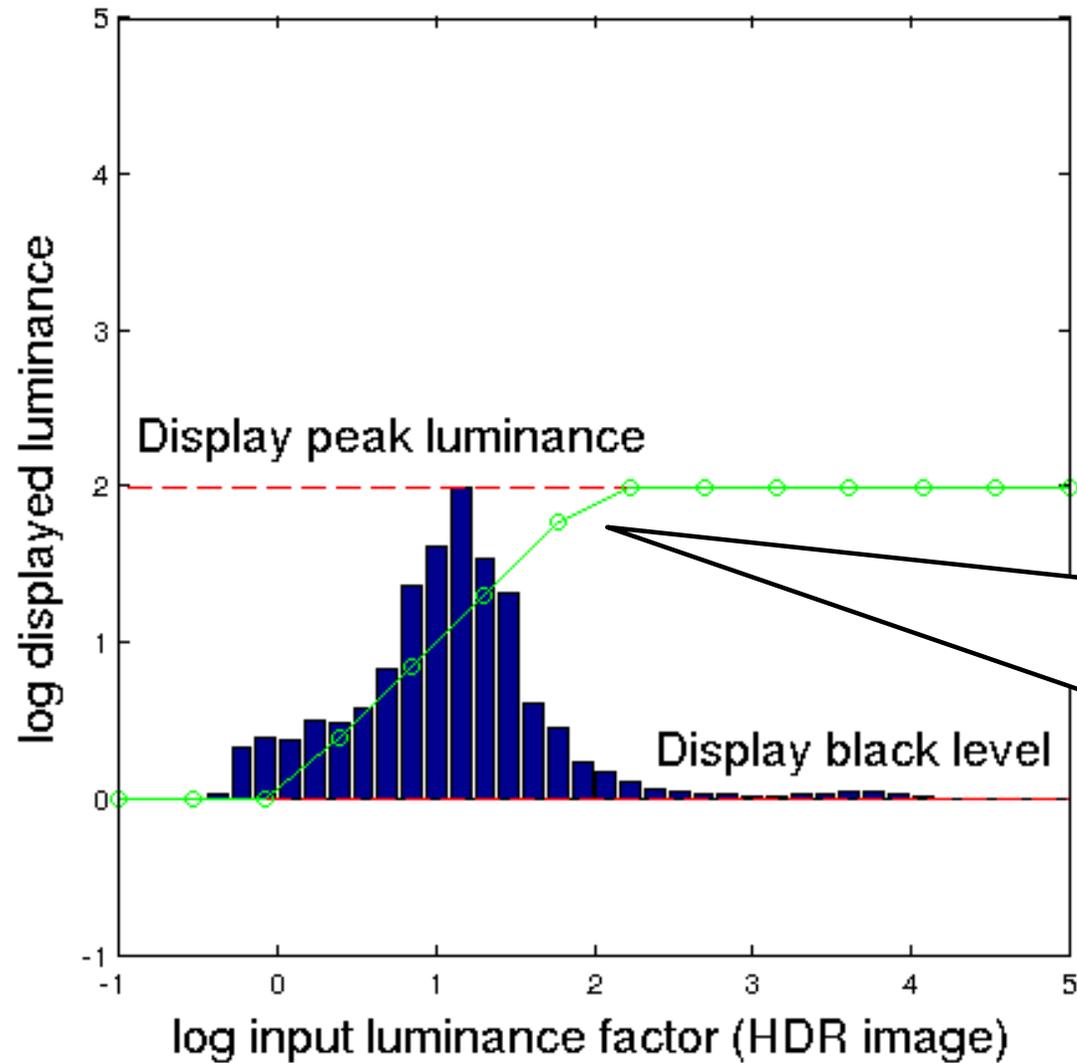

Best tone-mapping is the one which does not do anything, i.e. slope of the tone-mapping curves is equal to 1.

Tone-curve

But in practice contrast (slope) must be limited due to display limitations.

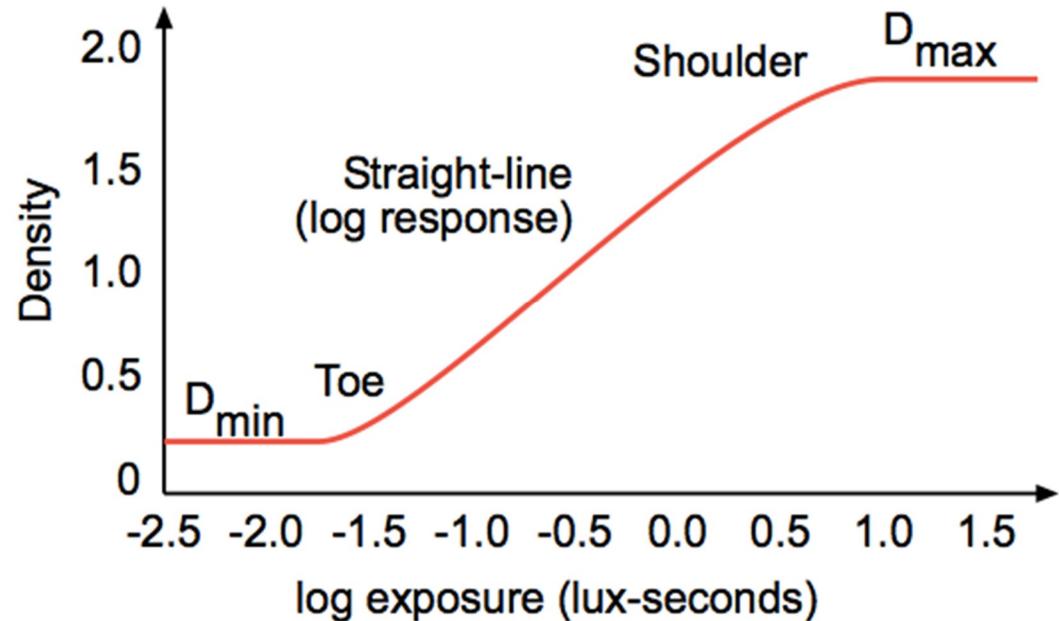

Tone-curve

Global tone-mapping is a compromise between clipping and contrast compression.

Sigmoidal tone-curves

- ▶ Very common in digital cameras
 - ▶ Mimic the response of analog film
 - ▶ Analog film has been engineered over many years to produce good tone-reproduction
- ▶ Fast to compute

Sigmoidal tone mapping

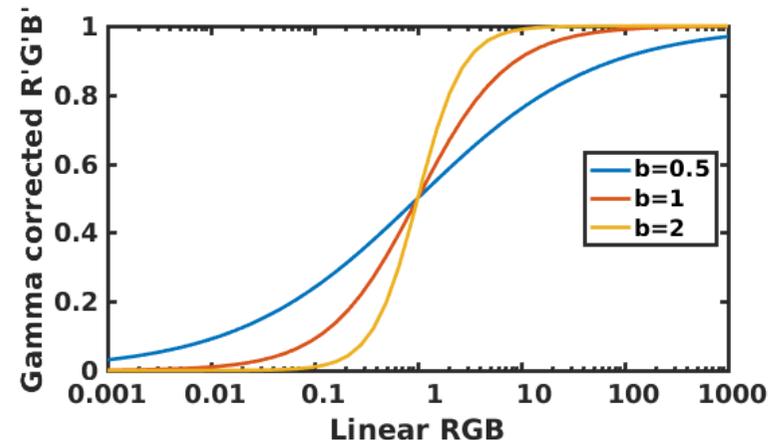

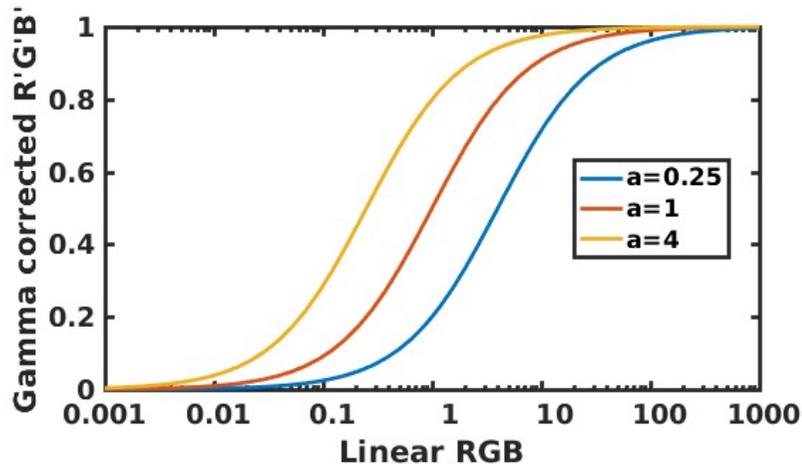

- ▶ Simple formula for a sigmoidal tone-curve:

$$R'(x, y) = \frac{R(x, y)^b}{\left(\frac{L_m}{a}\right)^b + R(x, y)^b}$$

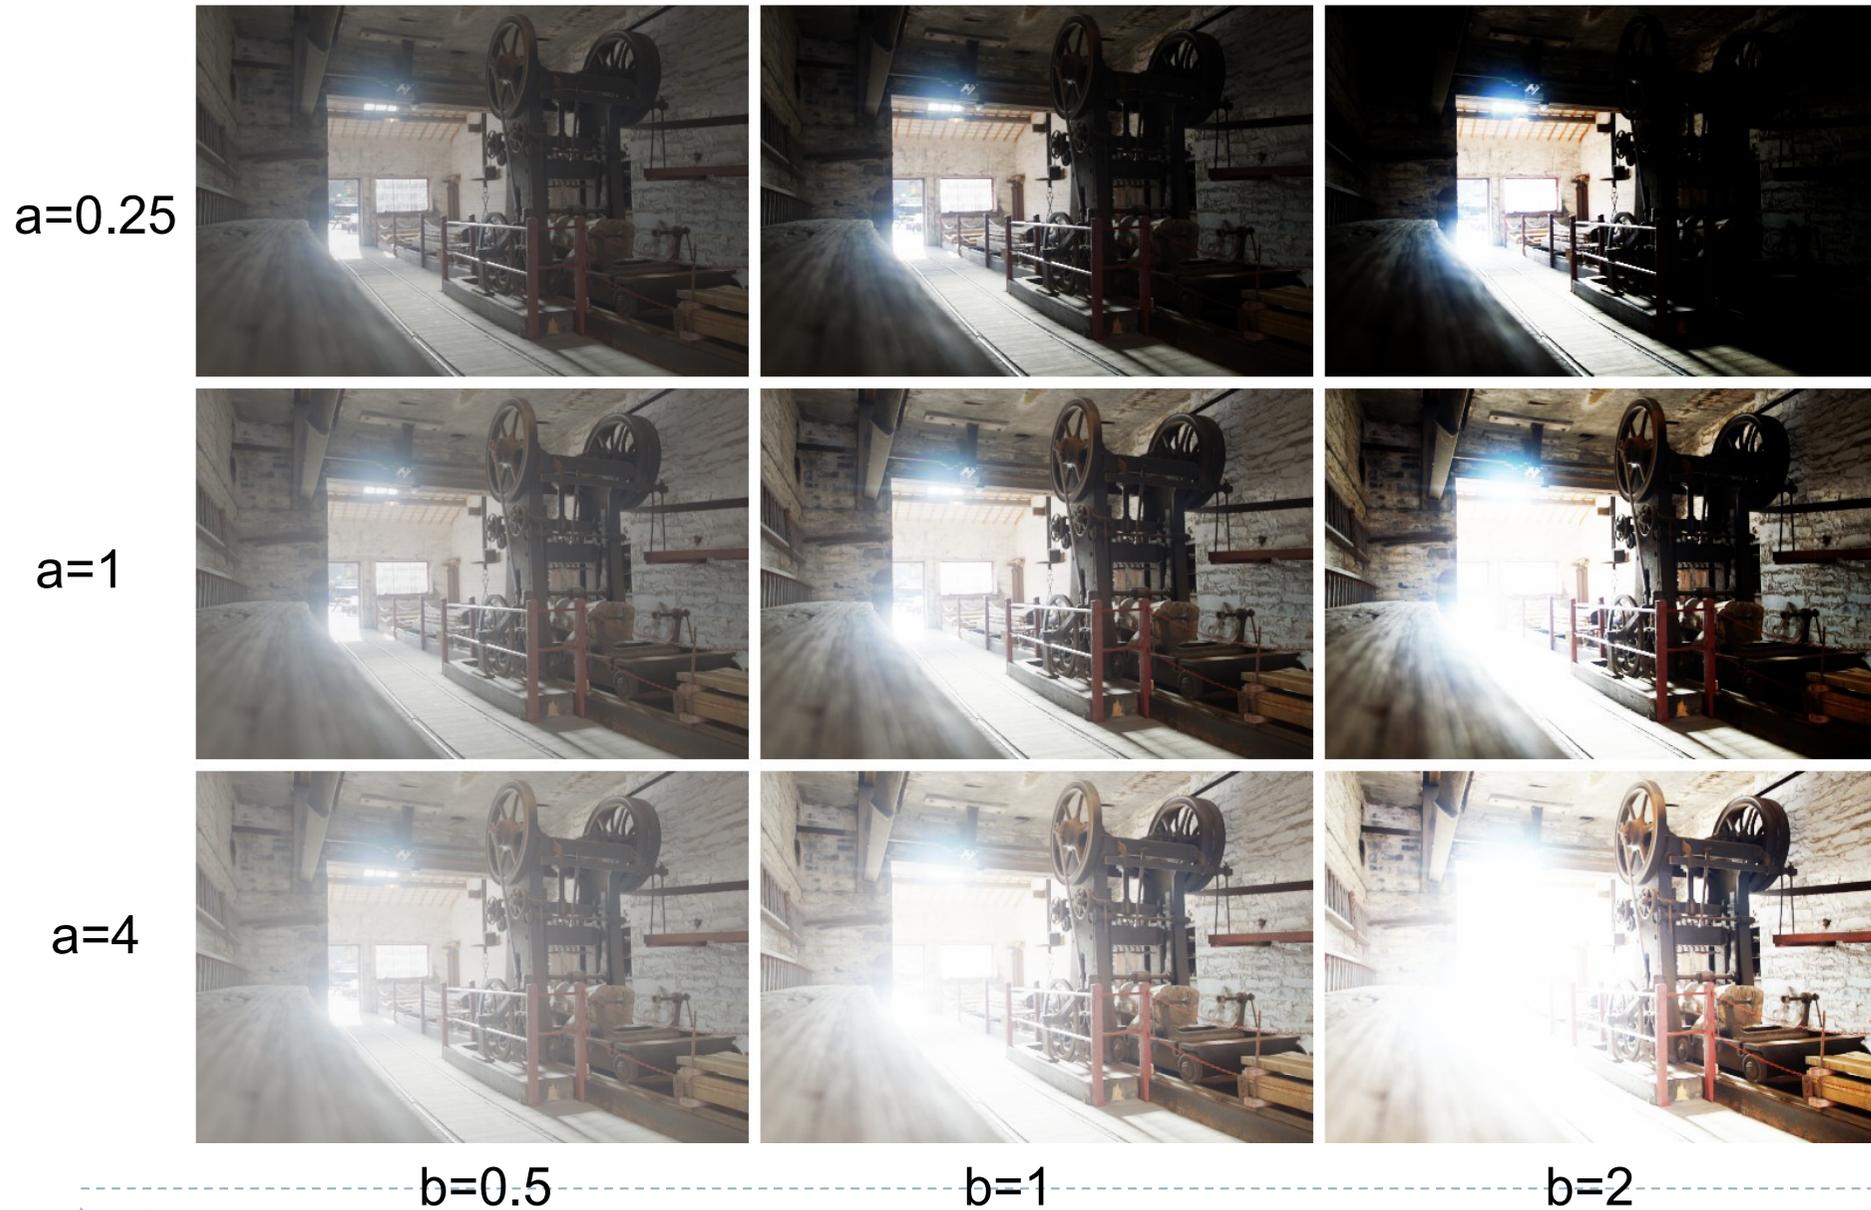

where L_m is the geometric mean (or mean of logarithms):

$$L_m = \exp\left(\frac{1}{N} \sum_{(x,y)} \ln(L(x, y))\right)$$

and $L(x, y)$ is the luminance of the pixel (x, y) .

Sigmoidal tone mapping example

Histogram equalization

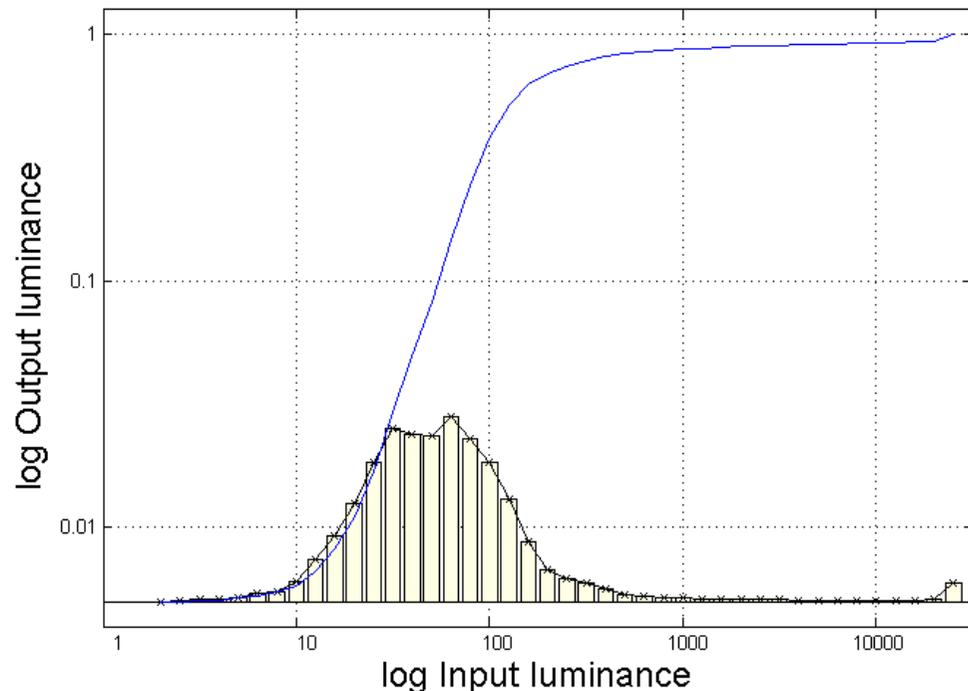

- ▶ 1. Compute normalized cumulative image histogram

$$c(I) = \frac{1}{N} \sum_{i=0}^I h(i) = c(I - 1) + \frac{1}{N} h(I)$$

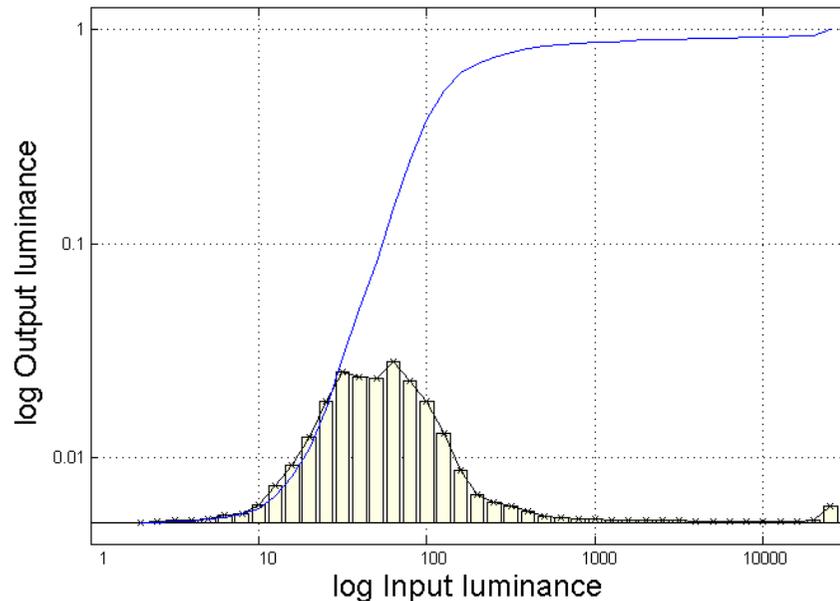

- ▶ For HDR, operate in the log domain
- ▶ 2. Use the cumulative histogram as a tone-mapping function

$$Y_{out} = c(Y_{in})$$

- ▶ For HDR, map the log-10 values to the $[-dr_{out}; 0]$ range
 - ▶ where dr_{out} is the target dynamic range (of a display)

Histogram equalization

- ▶ Steepest slope for strongly represented bins
- ▶ If many pixels have the same value - enhance contrast
- ▶ Reduce contrast, if few pixels
- ▶ Histogram Equalization distributes contrast distortions relative to the “importance” of a brightness level

CLAHE: Contrast-Limited Adaptive Histogram Equalization

- ▶ [Pizer et al. Adaptive histogram equalization and its variations. Comput Vision, Graph Image Process 1987], [Larson et al. 1997, IEEE TVCG]

Linear mapping

contrast

CLAHE: Contrast-Limited Adaptive Histogram Equalization

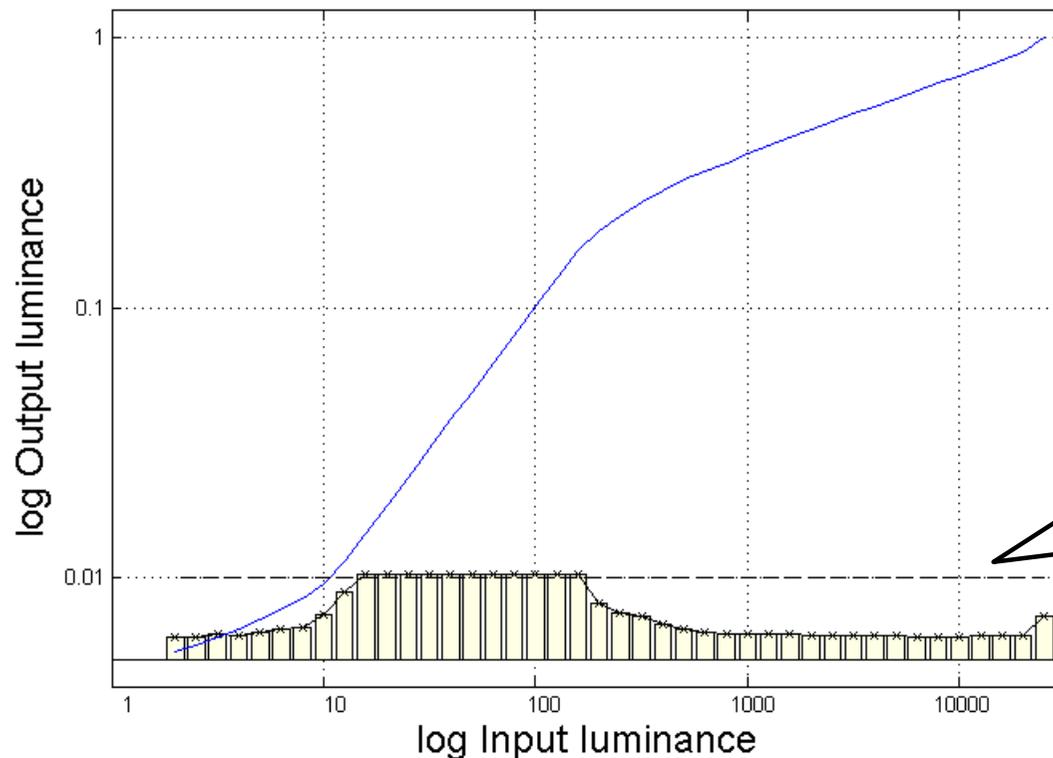

- ▶ Truncate the bins that exceed the ceiling;
- ▶ Distribute the removed counts to all bins;
- ▶ Repeat until converges

Ceiling, based on
the maximum
permissible
contrast

Techniques

- ▶ Arithmetic of HDR images
- ▶ Display model
- ▶ Tone-curve
- ▶ **Colour transfer**
- ▶ Base-detail separation
- ▶ Glare

Colour transfer in tone-mapping

- ▶ Many tone-mapping operators work on luminance, mean or maximum colour channel value
 - ▶ For speed
 - ▶ To avoid colour artefacts
- ▶ Colours must be transferred later from the original image
- ▶ Colour transfer in the linear RGB colour space:

The diagram illustrates the formula for colour transfer in the linear RGB colour space. It features the equation $R_{out} = \left(\frac{R_{in}}{L_{in}} \right)^s \cdot L_{out}$. A callout box on the left points to R_{out} and is labeled "Output color channel (red)". A callout box on the right points to the exponent s and is labeled "Saturation parameter". Another callout box on the right points to L_{out} and is labeled "Resulting luminance".

- ▶ The same formula applies to green (G) and blue (B) linear colour values

Colour transfer: out-of-gamut problem

- ▶ Colours often fall outside the colour gamut when contrast is compressed

Original image

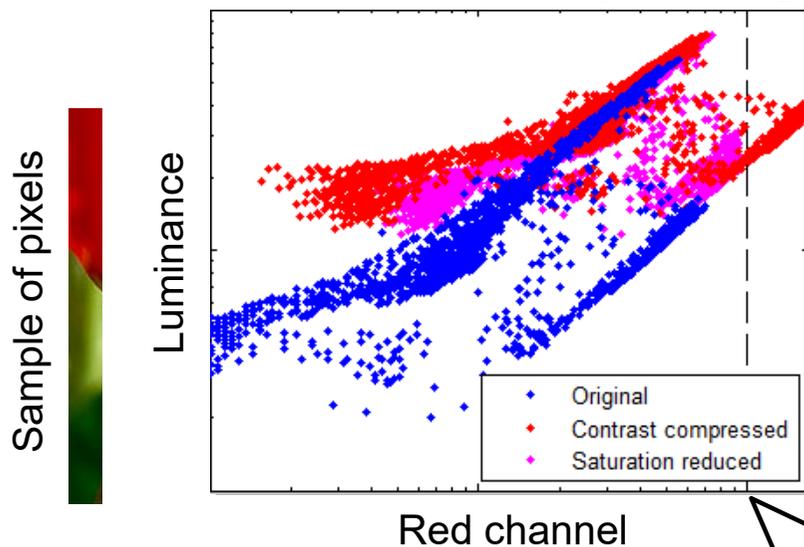

Contrast reduced ($s=1$)

Saturation reduced ($s=0.6$)

Colours before/after processing

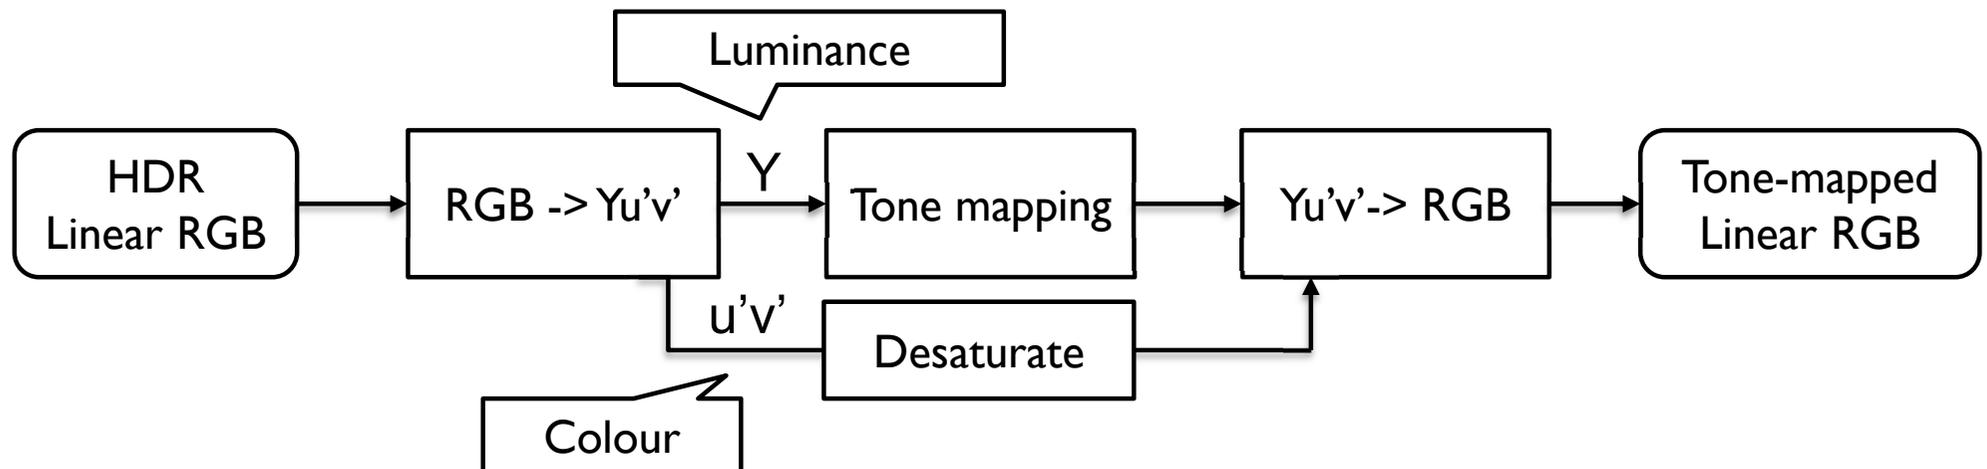

- ▶ Reduction in saturation is needed to bring the colors into gamut

Gamut boundary

Colour transfer: alternative method

- ▶ Colour transfer in linear RGB will alter resulting luminance
- ▶ Colours can be also transferred, and saturation adjusted using CIE $u'v'$ chromatic coordinates

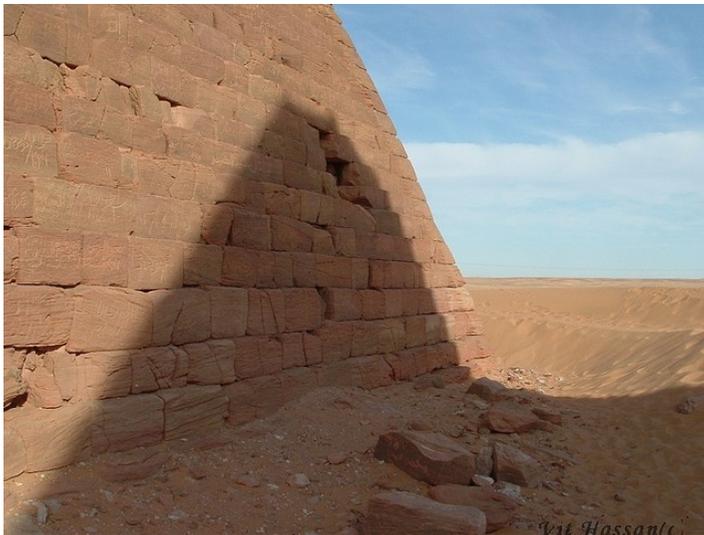

Chroma of the white

- ▶ To correct saturation:
$$u'_{out} = (u'_{in} - u'_w) \cdot s + u'_w$$
$$v'_{out} = (v'_{in} - v'_w) \cdot s + v'_w$$
$$u'_w = 0.1978$$
$$v'_w = 0.4683$$

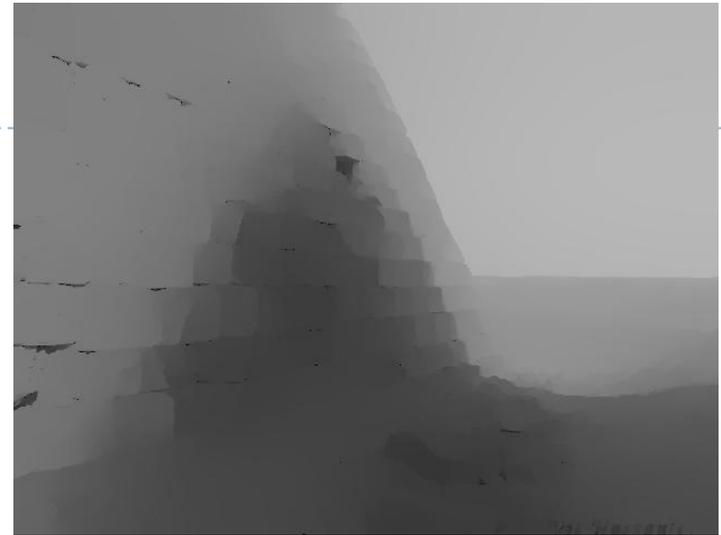

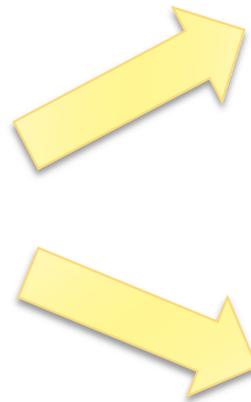

Techniques

- ▶ Arithmetic of HDR images
- ▶ Display model
- ▶ Tone-curve
- ▶ Colour transfer
- ▶ **Base-detail separation**
- ▶ Glare

Illumination & reflectance separation

Input

Illumination

Reflectance

$$Y = I \cdot R$$

Image

Illumination

Reflectance

Illumination and reflectance

Reflectance

- ▶ White $\approx 90\%$
- ▶ Black $\approx 3\%$

- ▶ Dynamic range $< 100:1$

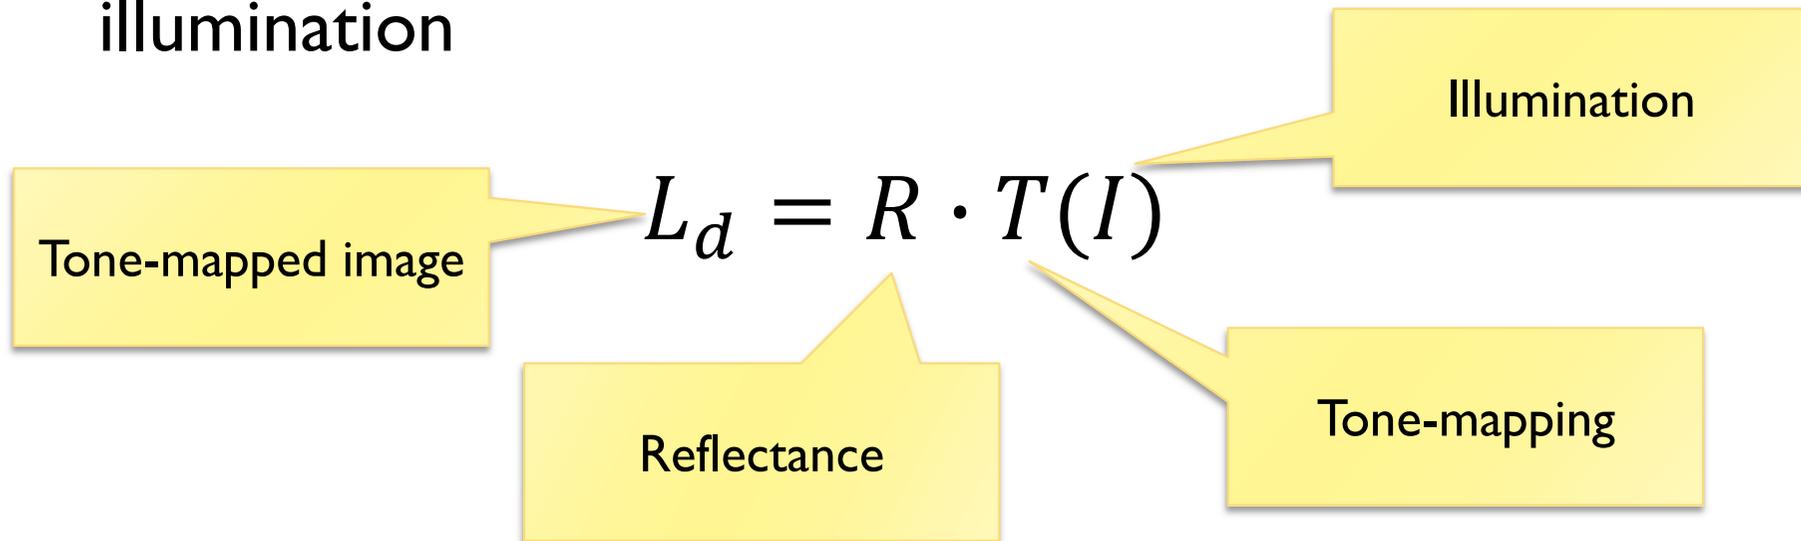

- ▶ Reflectance critical for object & shape detection

Illumination

- ▶ Sun $\approx 10^9 \text{ cd/m}^2$
- ▶ Lowest perceivable luminance $\approx 10^{-6} \text{ cd/m}^2$
- ▶ Dynamic range 10,000:1 or more
- ▶ Visual system partially discounts illumination

Reflectance & Illumination TMO

- ▶ Hypothesis: *Distortions in reflectance are more apparent than the distortions in illumination*
- ▶ Tone mapping could preserve reflectance but compress illumination

- ▶ for example:

$$L_d = R \cdot (I / L_{white})^c \cdot L_{white}$$

How to separate the two?

- ▶ (Incoming) illumination – slowly changing
 - ▶ except very abrupt transitions on shadow boundaries
- ▶ Reflectance – low contrast and high frequency variations

Gaussian filter

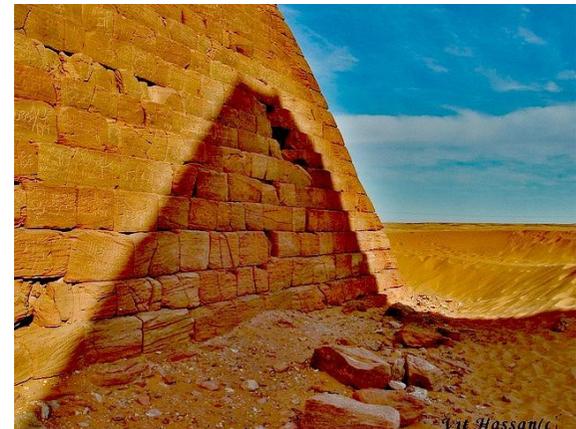

$$f(x) = \frac{1}{2\pi\sigma_s} e^{\frac{-x^2}{2\sigma_s^2}}$$

- ▶ First order approximation

- ▶ Blurs sharp boundaries
- ▶ Causes halos

Tone mapping
result

Bilateral filter

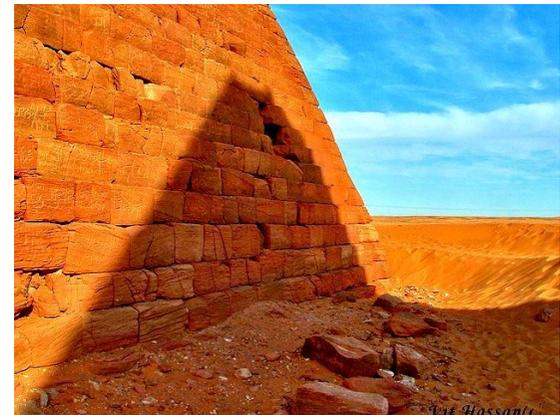

$$I_p \approx \frac{1}{k_s} \sum_{t \in \Omega} f(p-t) g(L_p - L_t) L_p$$

- ▶ Better preserves sharp edges

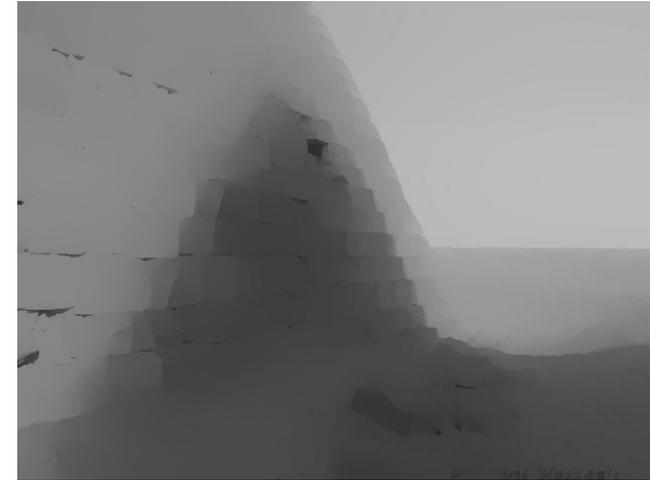

Tone mapping result

- ▶ Still some blurring on the edges
- ▶ Reflectance is not perfectly separated from illumination near edges

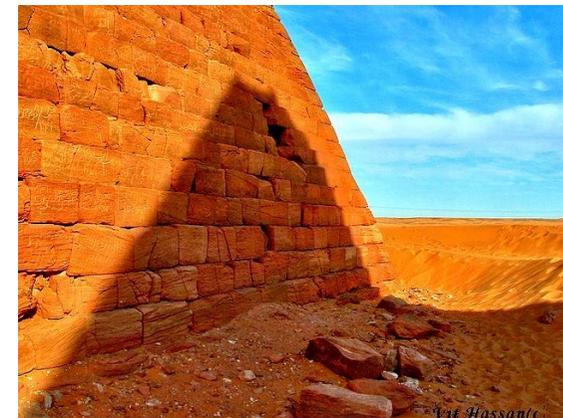

Weighted-least-squares (WLS) filter

- ▶ Stronger smoothing and still distinct edges

Tone mapping result

- ▶ Can produce stronger effects with fewer artifacts
- ▶ See „Advanced image processing” lecture

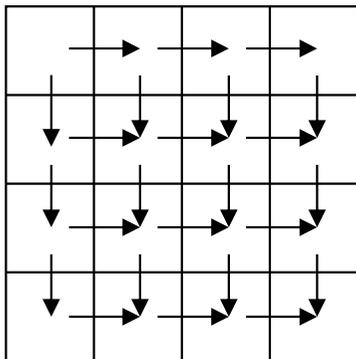

[Farbman et al., SIGGRAPH 2008]

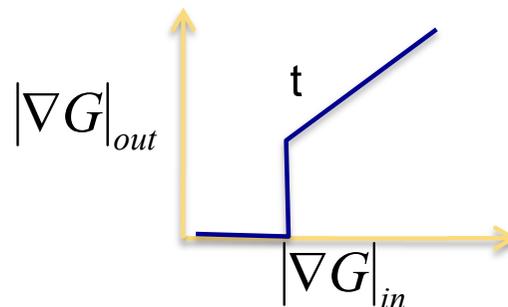

Retinex

- ▶ Retinex algorithm was initially intended to separate reflectance from illumination [Land 1964]
 - ▶ There are many variations of Retinex, but the general principle is to eliminate from an image small gradients, which are attributed to the illumination

1 step: compute gradients in log domain

2nd step: set to 0 gradients less than the threshold

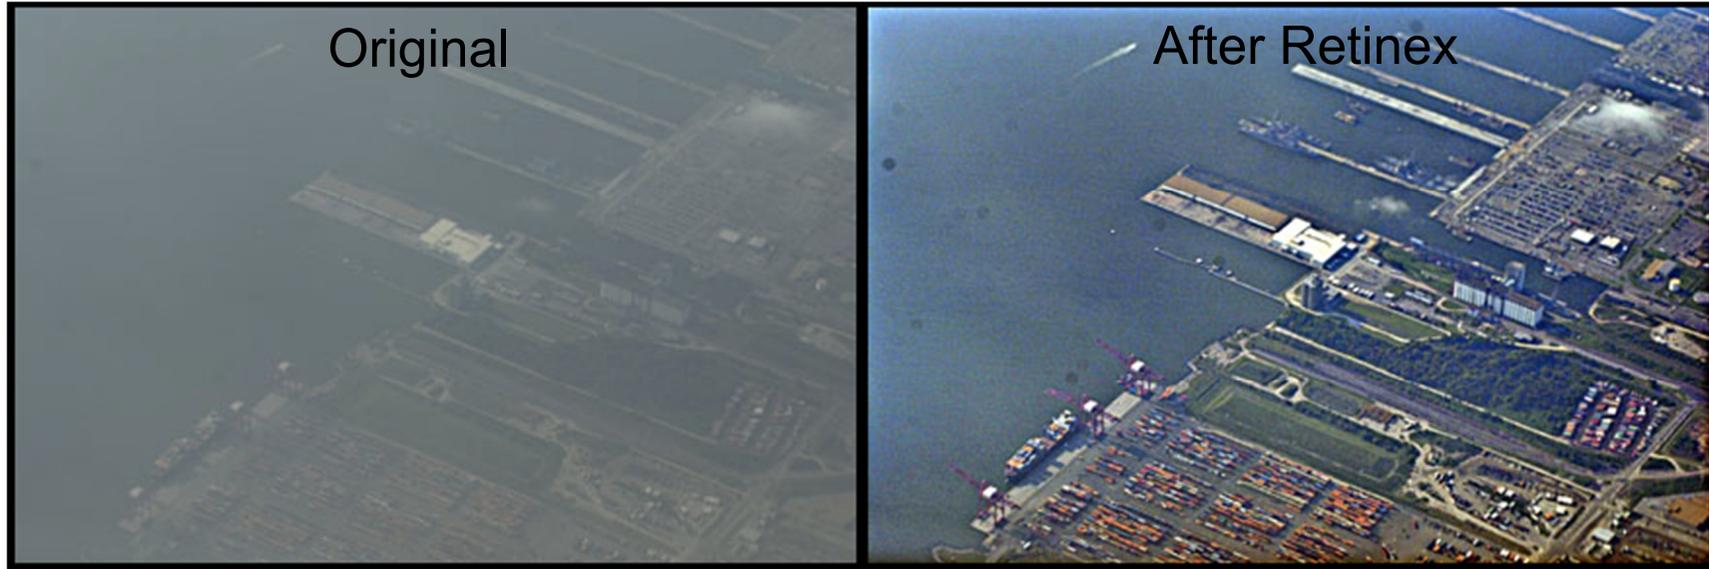

3rd step: reconstruct an image from the vector field

$$\nabla^2 I = \text{div } G$$

For example by solving the Poisson equation

Retinex examples

From: <http://dragon.larc.nasa.gov/retinex/757/>

From: http://www.ipol.im/pub/algo/lmps_retinex_poisson_equation/#ref_1

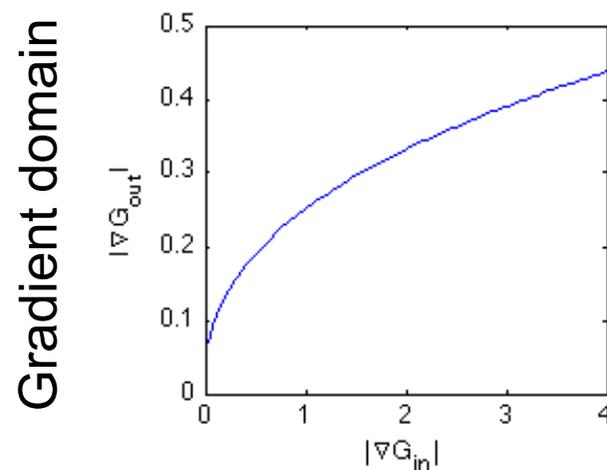

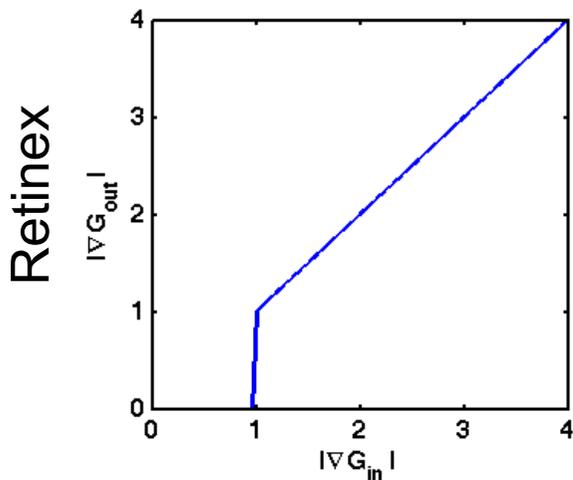

Gradient domain HDR compression

[Fattal et al.,
SIGGRAPH 2002]

- ▶ Similarly to Retinex, it operates on log-gradients
- ▶ But the function amplifies small contrast instead of removing it

- Contrast compression achieved by global contrast reduction
 - Enhance reflectance, then compress everything

Techniques

- ▶ Arithmetic of HDR images
- ▶ Display model
- ▶ Tone-curve
- ▶ Colour transfer
- ▶ Base-detail separation
- ▶ **Glare**

Examples of simulated glare

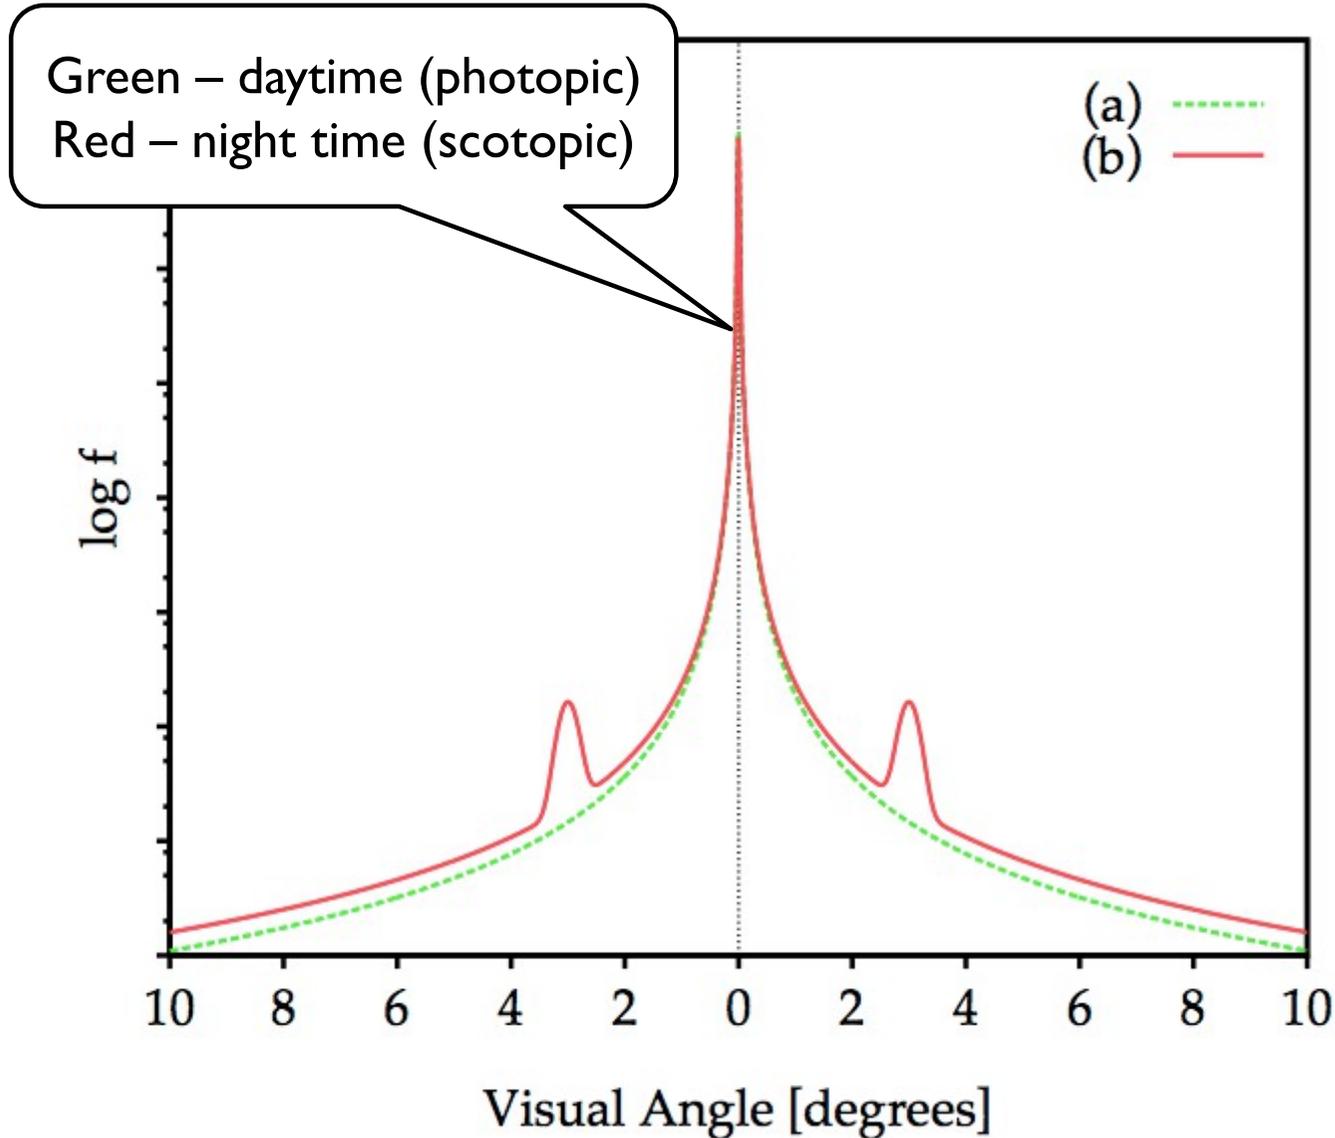

[From Ritschel et al, Eurographics 2009]

Temporal glare

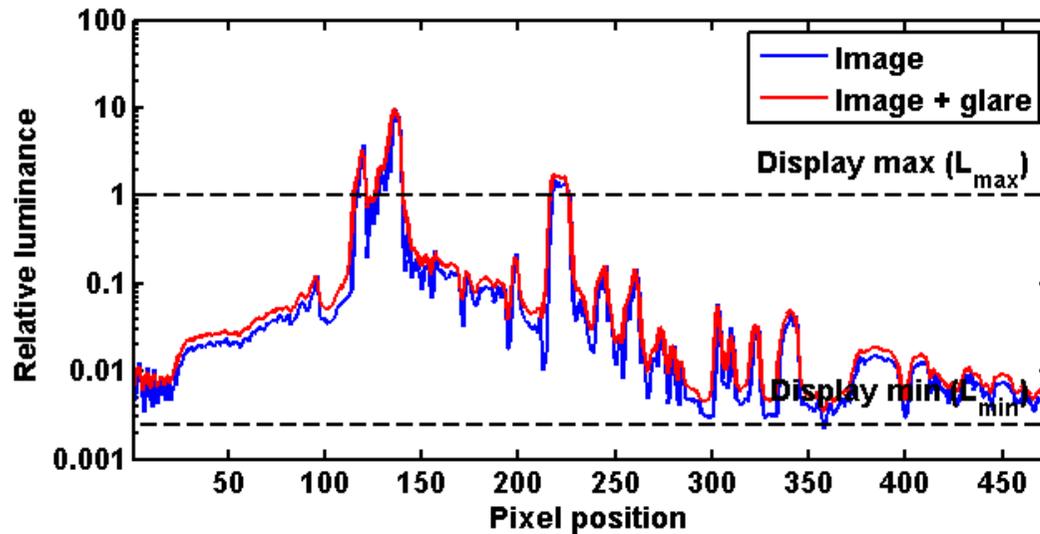

Point Spread Function of the eye

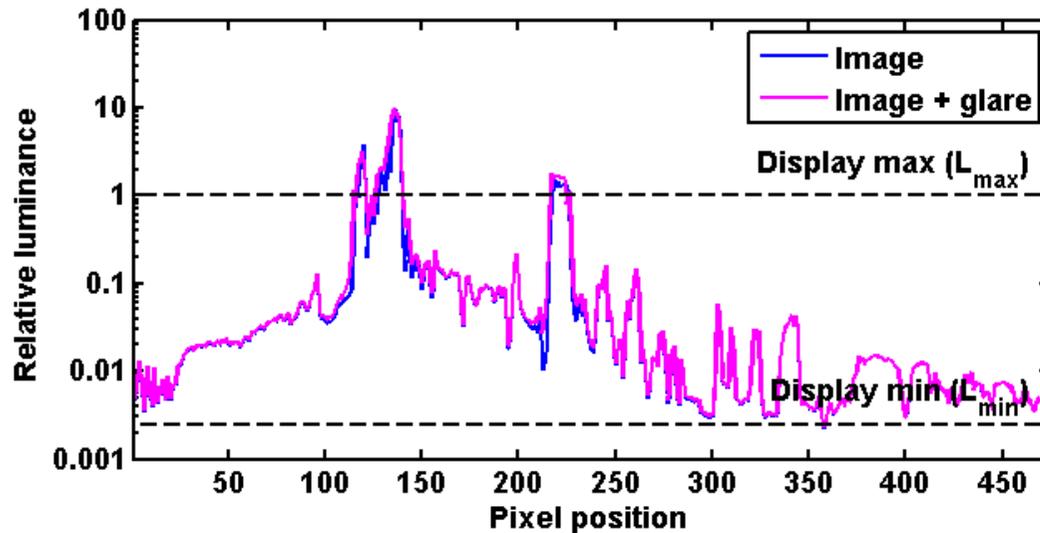

- ▶ What portion of the light is scattered towards a certain visual angle
- ▶ To simulate:
 - ▶ construct a digital filter
 - ▶ convolve the image with that filter

From: Spencer, G. et al. 1995.
Proc. of SIGGRAPH. (1995)

Selective application of glare

- ▶ A) Glare applied to the entire image
 $I_g = I * G$ (Glare kernel (PSF))
- ▶ Reduces image contrast and sharpness

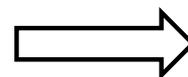

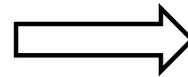

- B) Glare applied only to the clipped pixels
 $I_g = I + I_{clipped} * G - I_{clipped}$
where $I_{clipped} = \begin{cases} I & \text{for } I > 1 \\ 0 & \text{otherwise} \end{cases}$
- Better image quality

Selective application of glare

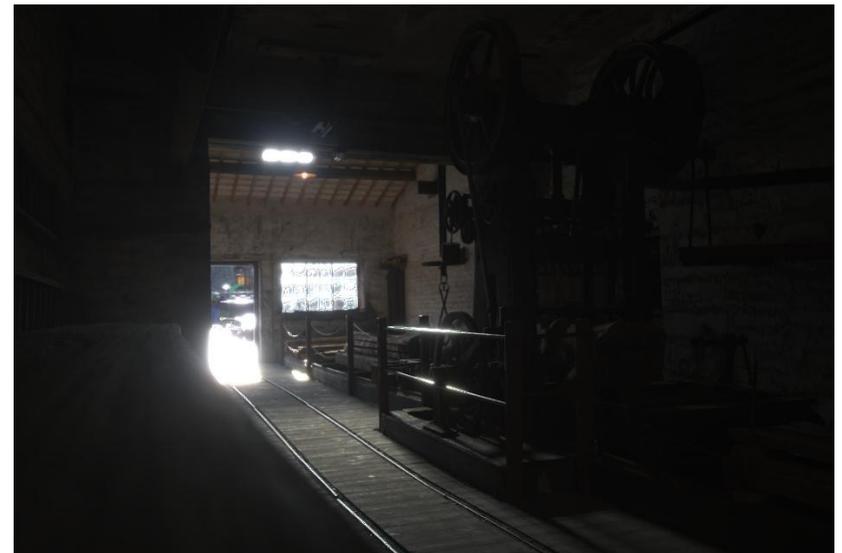

A) Glare applied to the entire image

Original image

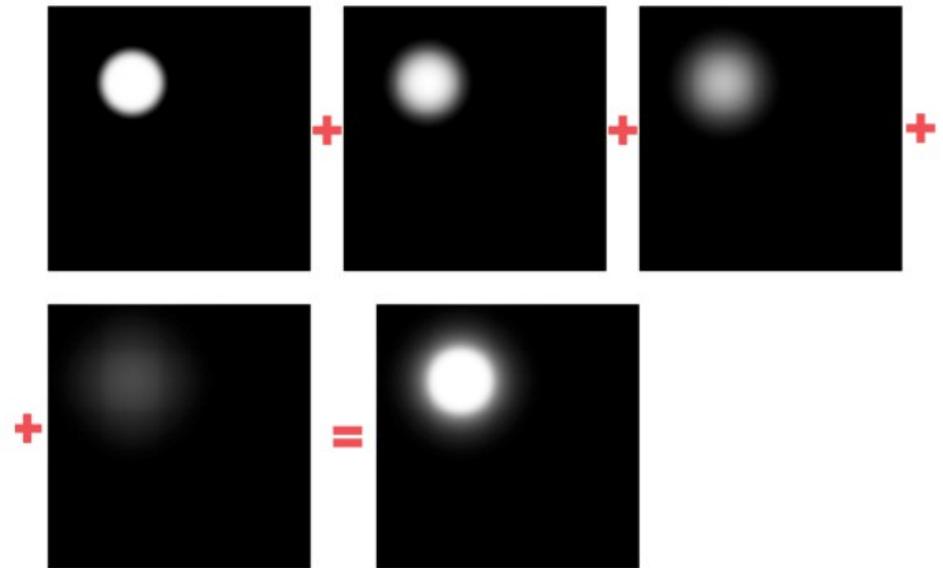

B) Glare applied to clipped pixels only

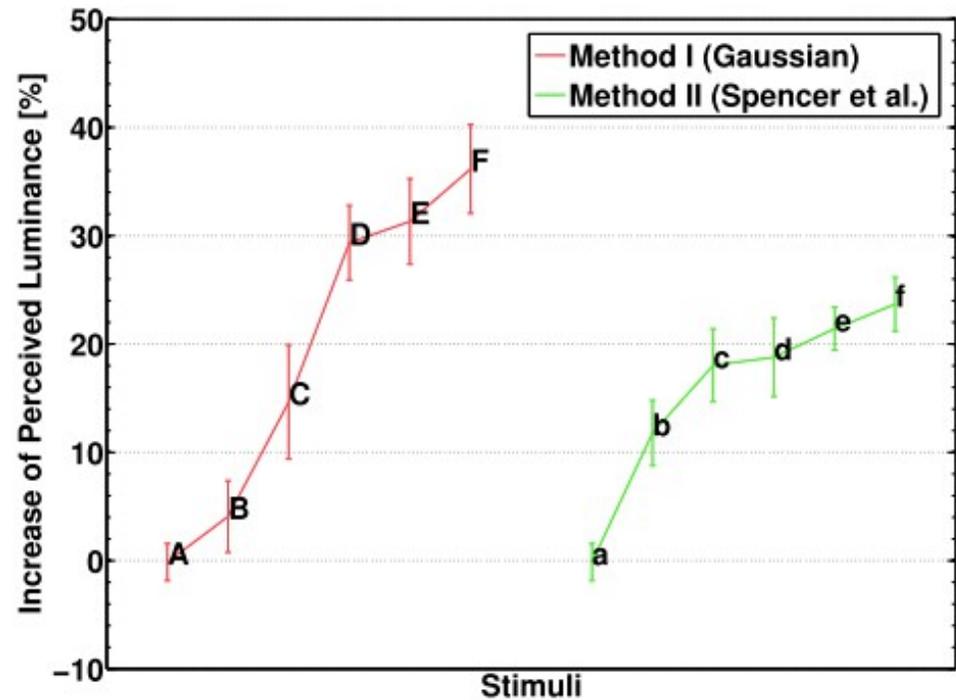

Glare (or bloom) in games

- ▶ Convolution with large, non-separable filters is too slow
- ▶ The effect is approximated by a combination of Gaussian filters
 - ▶ Each filter with different “sigma”
- ▶ The effect is meant to look good, not be accurate model of light scattering
- ▶ Some games simulate camera rather than the eye

Does the exact shape of the PSF matter?

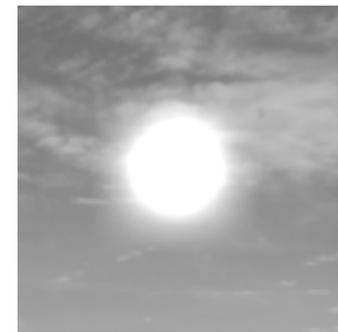

- ▶ The illusion of increased brightness works even if the PSF is very different from the PSF of the eye

red - Gaussian

green - accurate

Nintendo
Virtual Boy

VR explosion
Oculus, Sony, HTC, MS, ...

Ivan Sutherland's HMD

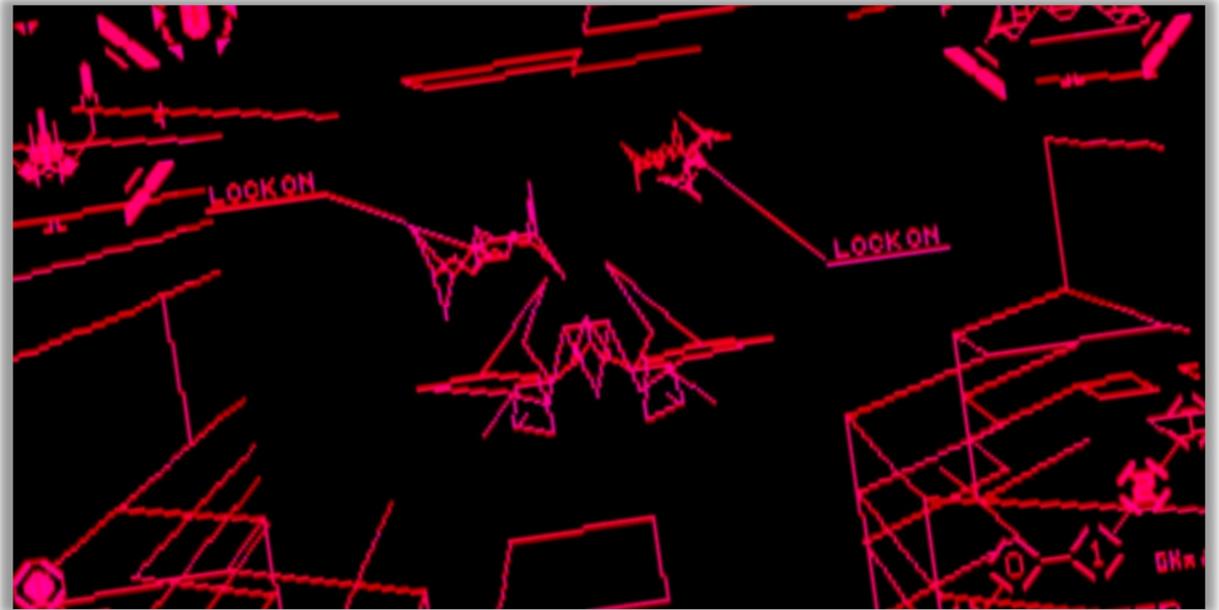

- optical see-through AR, including:
 - displays (2x 1" CRTs)
 - rendering
 - head tracking
 - interaction
 - model generation
- computer graphics
- human-computer interaction

I. Sutherland "A head-mounted three-dimensional display", Fall Joint Computer Conference 1968

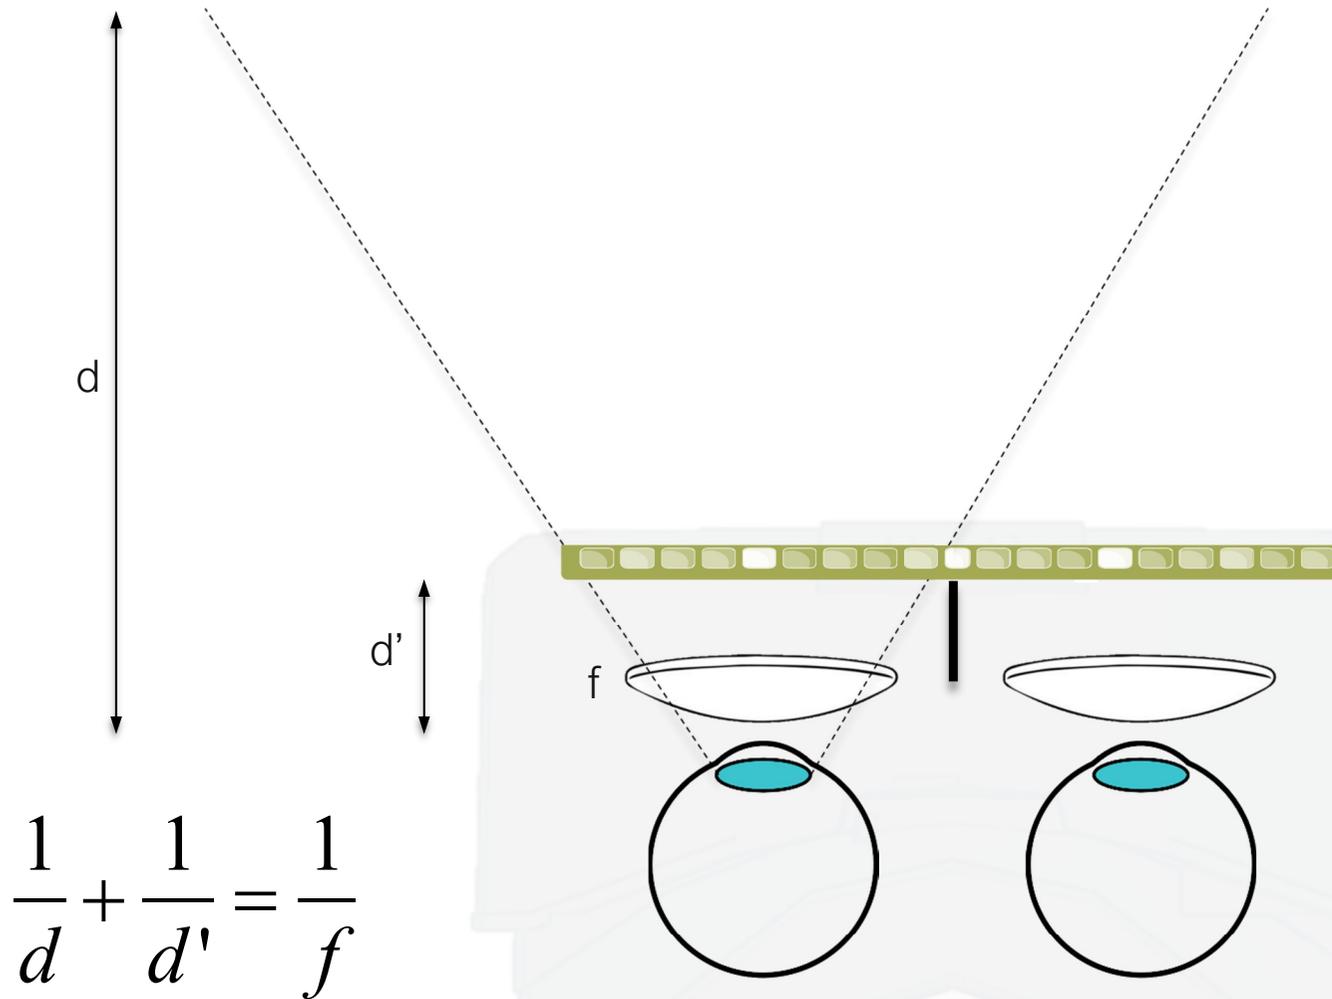

Nintendo Virtual Boy

- computer graphics & GPUs were not ready yet!

Game: Red Alarm

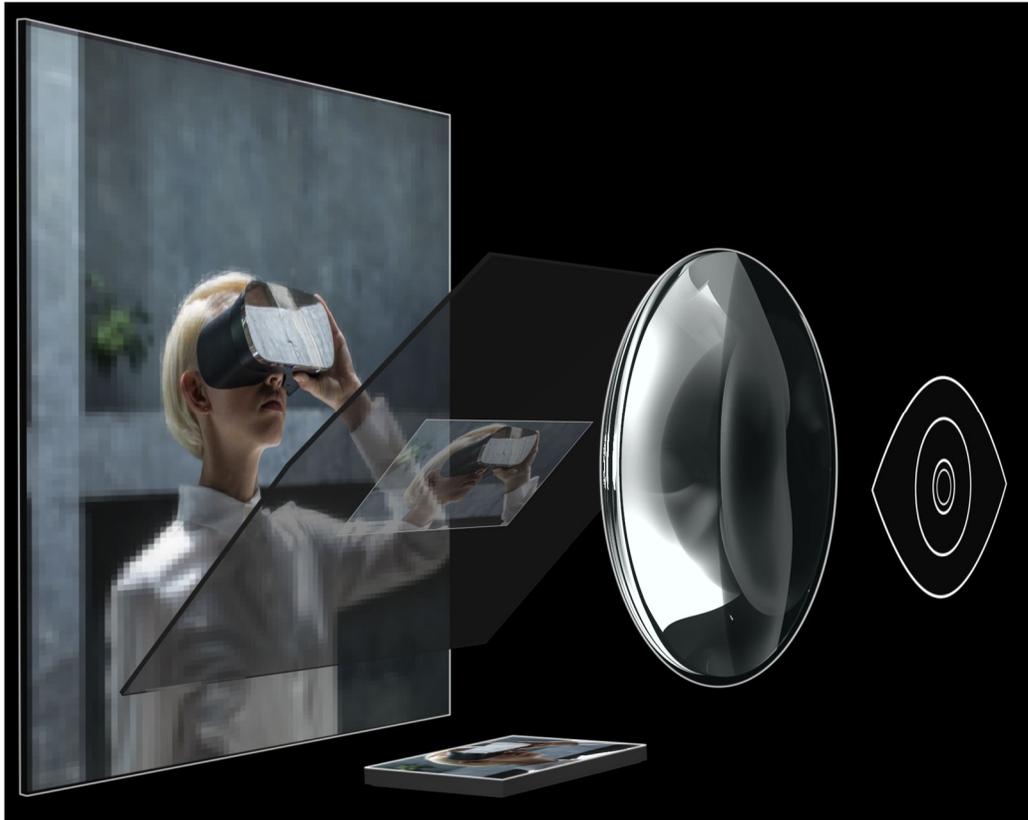

Virtual Image

Problems:

- fixed focal plane
- no focus cues ☹️
- cannot drive accommodation with rendering!
- limited resolution

A dual-resolution display

- ▶ High resolution image in the centre, low resolution fills wide field-of-view
- ▶ Two displays combined using a beam-splitter
- ▶ Image from: <https://varjo.com/bionic-display/>

Meta 2
(not the current Meta/Facebook)

Intel Vaunt

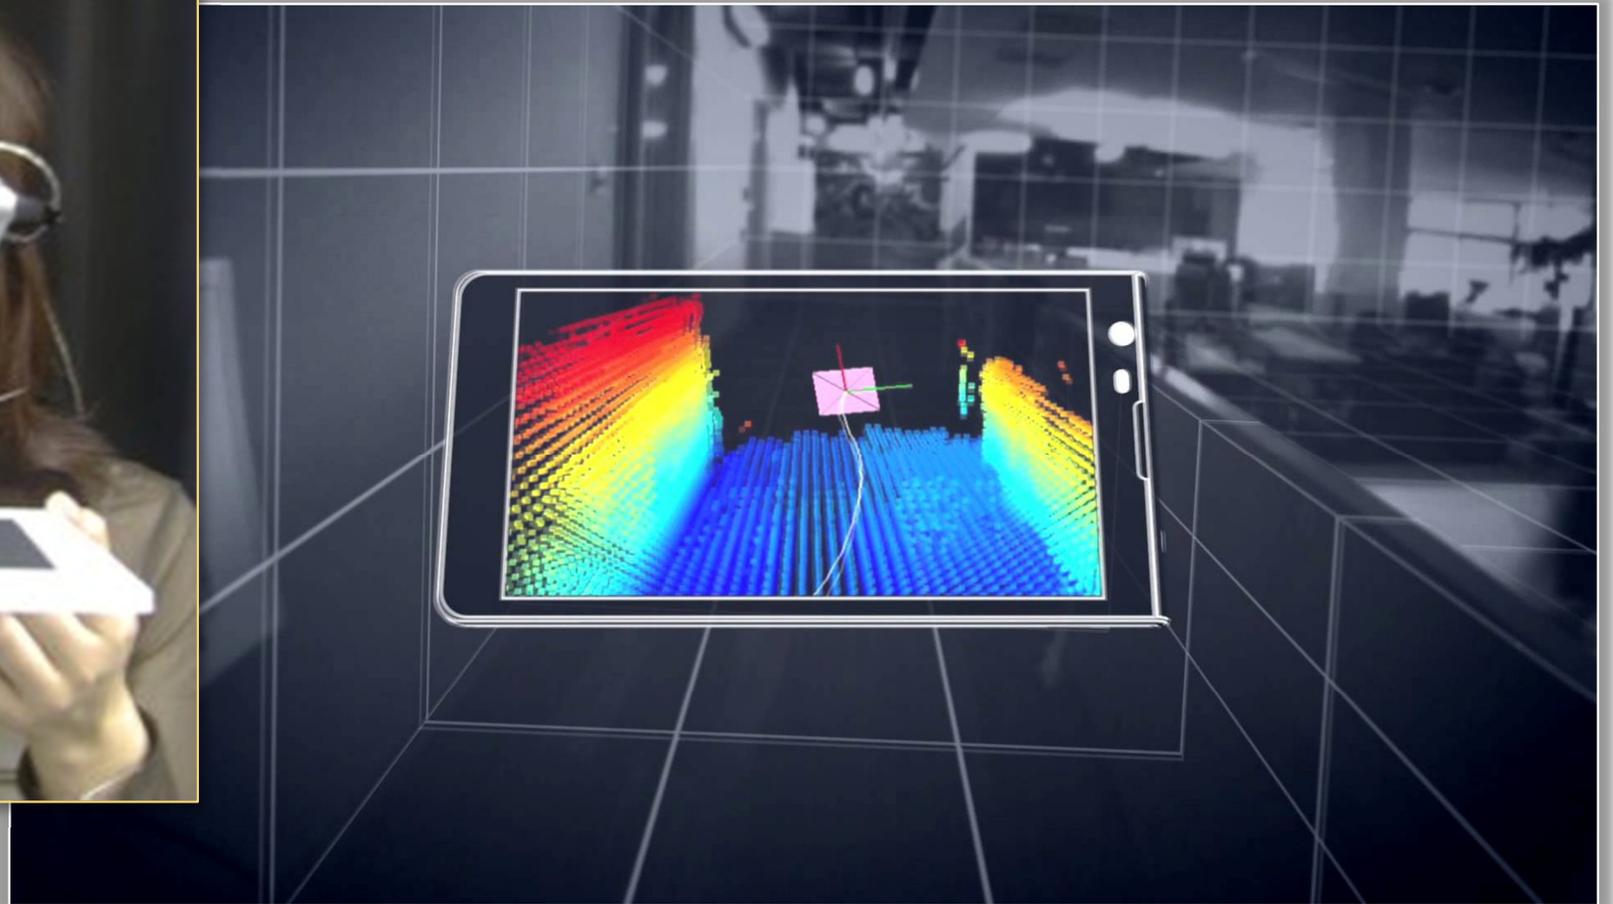

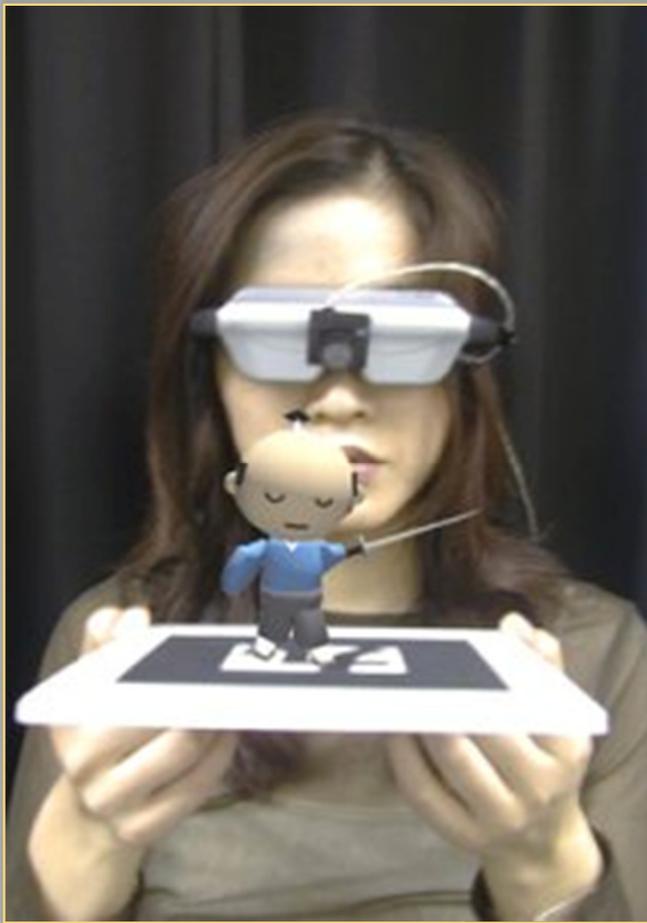

Google Glass

(Some) challenges of optical see-through AR

- ▶ **Transparency, lack of opacity**
 - ▶ Display light is mixed with environment light
- ▶ **Resolution and field-of-view**
- ▶ **Eye-box**
 - ▶ The volume in which the pupil needs to see the image
- ▶ **Brightness and contrast**
- ▶ **Blocked vision – forward and periphery (safety)**
- ▶ **Power efficiency**
- ▶ **Size, weight and weight distribution**
 - ▶ 50 grams are comfortable for long periods
- ▶ **Social issues, price, vision correction, individual variability...**

More resources: <https://kguttag.com/>

Video pass-through AR: ARCore, ARKit, ARToolKit, ...

Video pass-through AR

Pros:

- ▶ Better virtual image quality
- ▶ Occlusions are easy
- ▶ Simpler, less expensive optics
- ▶ Virtual image not affected by ambient light
- ▶ AR/VR in one device

Cons:

- ▶ Vergence-accommodation conflict (see next lecture)
- ▶ Lower brightness, dynamic range and resolution than real-world
- ▶ Motion to photon delay
- ▶ Real-world images must be warped for the eye position (artifacts)
- ▶ Peripheral vision is occluded
 - ▶ Or display if affected by ambient light

Meta Project Cambria (Quest Pro)

VR/AR challenges

- ▶ Latency (next lecture)
- ▶ Tracking
- ▶ 3D Image quality and resolution
- ▶ Reproduction of depth cues (last lecture)
- ▶ Rendering & bandwidth
- ▶ Simulation/cyber sickness
- ▶ Content creation
 - ▶ Game engines
 - ▶ Image-Based-Rendering

Simulation sickness

- ▶ Conflict between vestibular and visual systems
 - ▶ When camera motion inconsistent with head motion
 - ▶ Frame of reference (e.g. cockpit) helps
 - ▶ Worse with larger FOV
 - ▶ Worse with high luminance and flicker

Display Technologies

Advanced Graphics and Image Processing

Rafał Mantiuk

Computer Laboratory, University of Cambridge

Overview

- ▶ **Temporal aspects**
 - ▶ Latency in VR
 - ▶ Eye-movement
 - ▶ Hold-type blur
- ▶ **2D displays**
 - ▶ 2D spatial light modulators
 - ▶ High dynamic range displays

Latency in VR

▶ Sources of latency in VR

- ▶ IMU ~1 ms
 - ▶ Inertial Measurement Unit
- ▶ sensor fusion, data transfer
- ▶ rendering: depends on complexity of scene & GPU – a few ms
- ▶ data transfer again
- ▶ Display
 - ▶ 60 Hz = 16.6 ms;
 - ▶ 70 Hz = 14.3 ms;
 - ▶ 120 Hz = 8.3 ms.

▶ Target latency

- ▶ Maximum acceptable: 20ms
- ▶ Much smaller (5ms) desired for interactive applications

▶ Example

- ▶ 16 ms (display) + 16 ms (rendering) + 4 ms (orientation tracking) = 36 ms latency total
- ▶ At 60 deg/s head motion, 1Kx1K, 100deg fov display:
 - ▶ 19 pixels error
 - ▶ Too much

Post-rendering image warp (time warp)

- ▶ To minimize end-to-end latency
- ▶ The method:
 - ▶ get current camera pose
 - ▶ render into a larger raster than the screen buffer
 - ▶ get new camera pose
 - ▶ warp rendered image using the latest pose, send to the display
 - ▶ 2D image translation
 - ▶ 2D image warp
 - ▶ 3D image warp
- ▶ Original paper from Mark et al. 1997, also Darsa et al. 1997
 - ▶ Meta:Asynchronous Time Warp

Eye movement - basics

Fixation

Drift: 0.15-0.8 deg/s

Eye movement - basics

Saccade

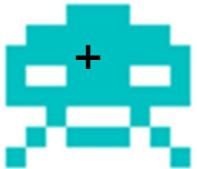

160-300 deg/s

Eye movement - basics

Smooth Pursuit Eye Motion (SPEM)

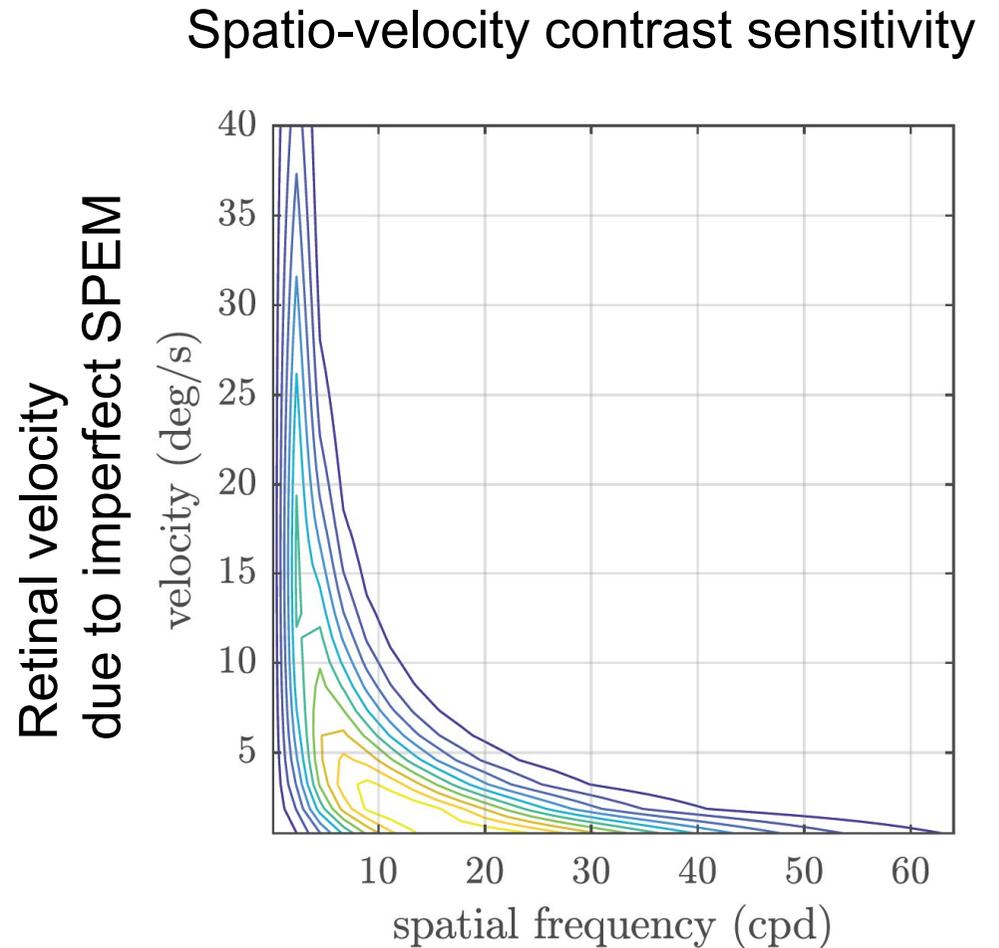

Up to 80 deg/s

The tracking is imperfect

- especially at higher velocities
- and for unpredictable motion

Retinal velocity

- ▶ The eye tracks moving objects
 - ▶ Smooth Pursuit Eye Motion (SPEM) stabilizes images on the retina
 - ▶ But SPEM is imperfect
- ▶ Loss of sensitivity mostly caused by imperfect SPEM
 - ▶ SPEM worse at high velocities

Kelly's model [1979]

Motion sharpening

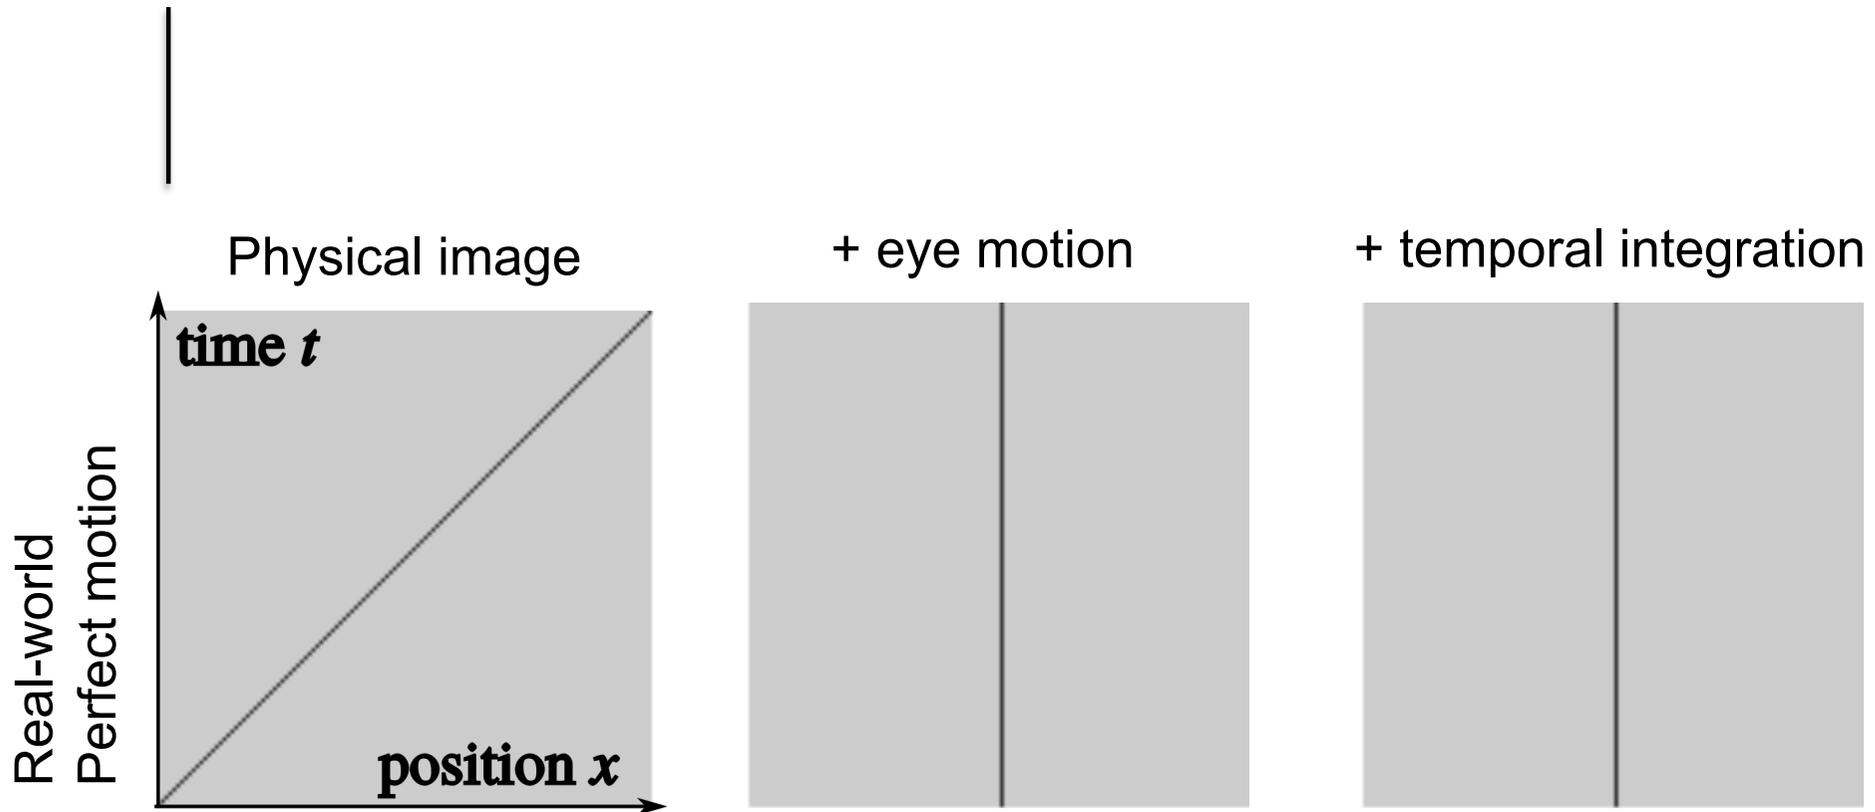

- ▶ The visual system “sharpens” objects moving at speeds of 6 deg/s or more

- ▶ Potentially a reason why VR appears sharper than it actually is

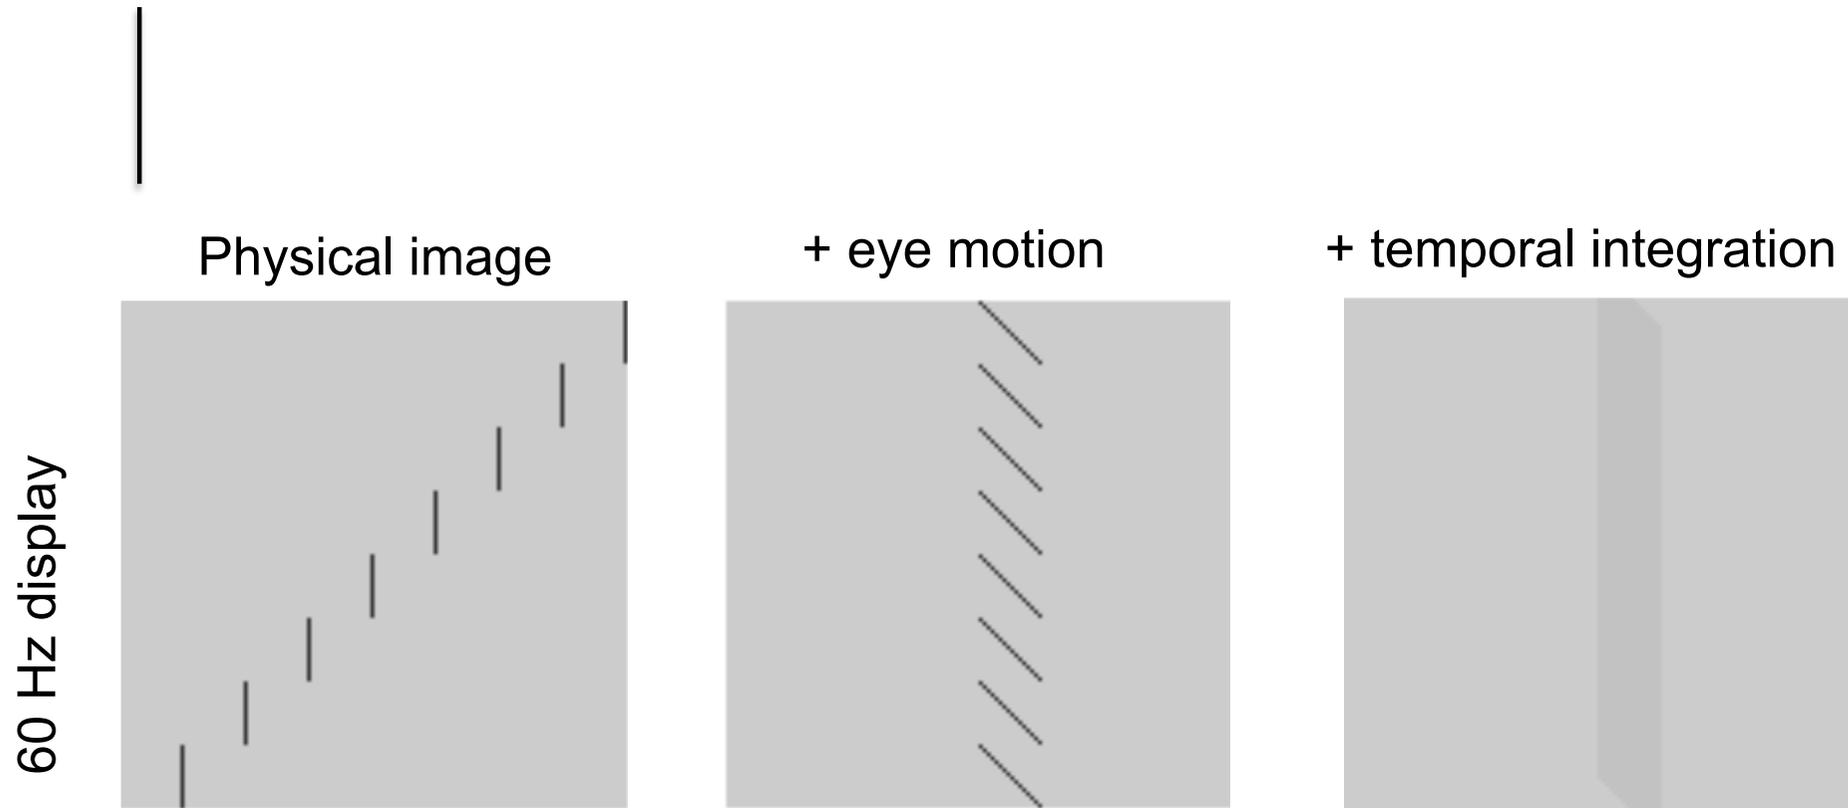

Hold-type blur

- ▶ The eye smoothly follows a moving object
- ▶ But the image on the display is “frozen” for $1/60^{\text{th}}$ of a second

Hold-type blur

- ▶ The eye smoothly follows a moving object
- ▶ But the image on the display is “frozen” for 1/60th of a second

Original scene

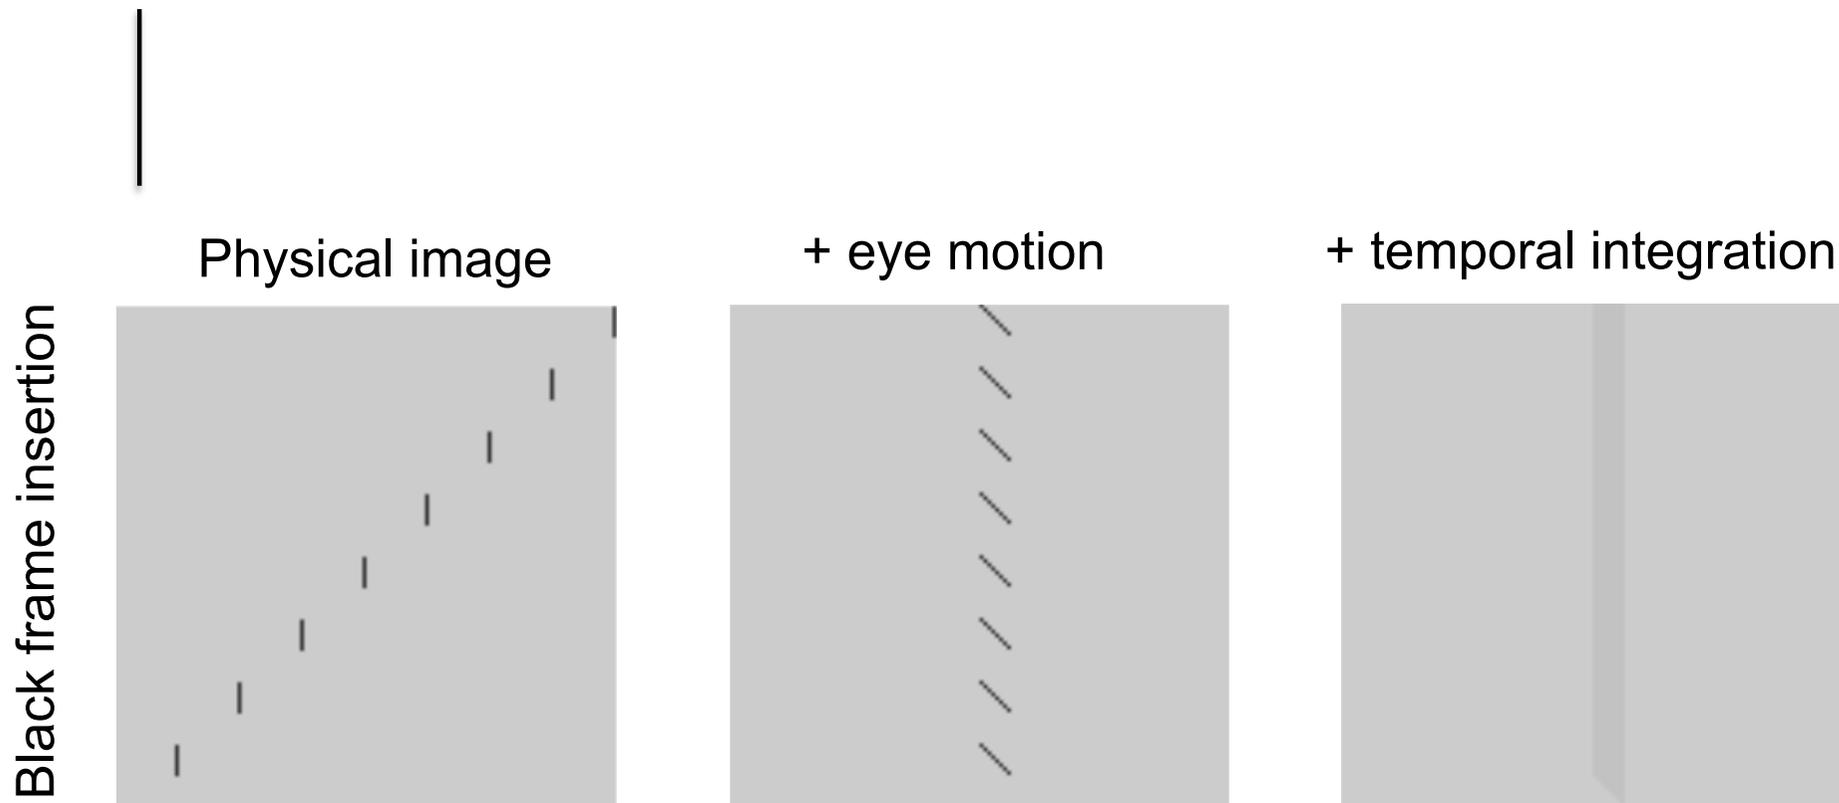

With hold-type blur

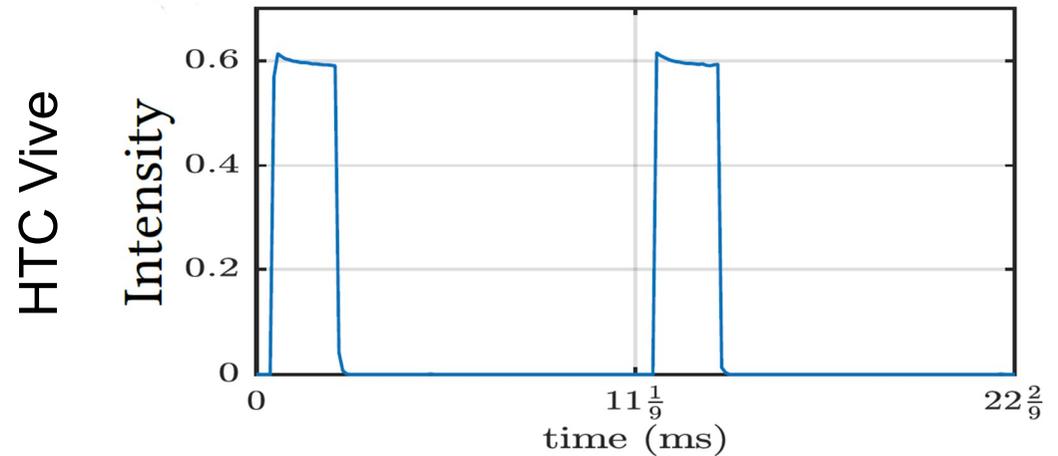

Hold-type blur

- ▶ The eye smoothly follows a moving object
- ▶ But the image on the display is “frozen” for 1/60th of a second

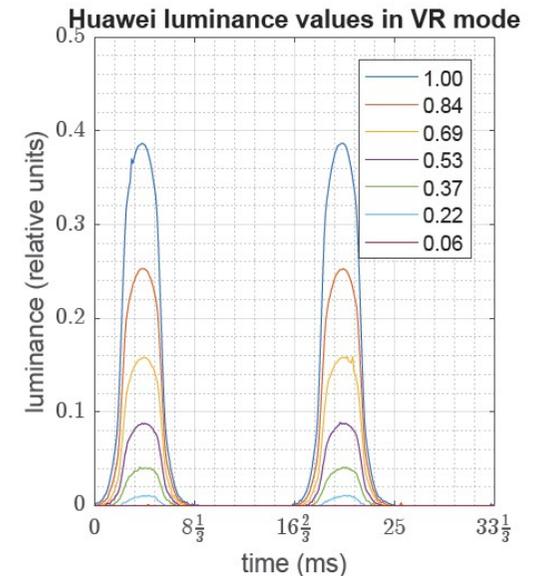

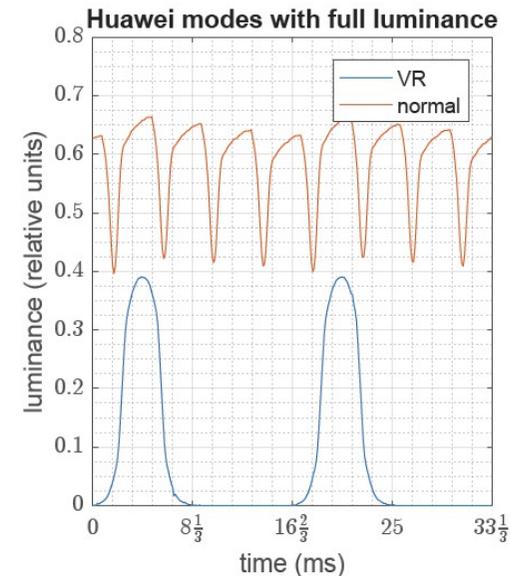

Low persistence displays

- ▶ Most VR displays flash an image for a fraction of frame duration
- ▶ This reduces hold-type blur
- ▶ And also reduces the perceived lag of the rendering

Mate 9 Pro + DayDream

Black frame insertion

- ▶ Which invader appears sharper?

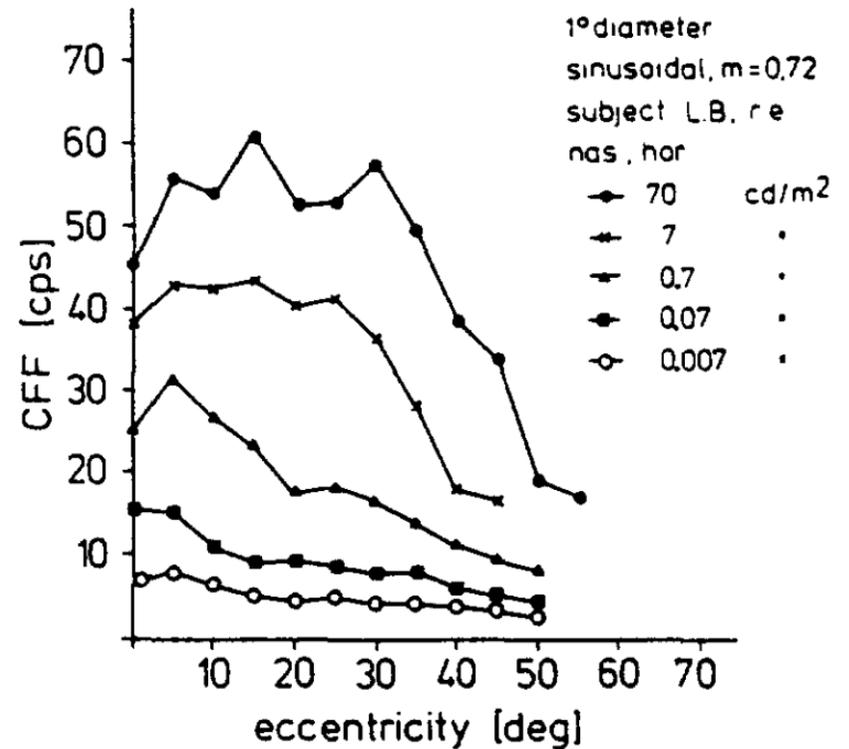

- ▶ A similar idea to low-persistence displays in VR
- ▶ Reduces hold-type blur

Flicker

▶ Critical Flicker Frequency

- ▶ The lowest frequency at which flickering stimulus appears as a steady field
- ▶ Measured for full-on / off presentation
- ▶ Strongly depends on luminance – big issue for HDR VR headsets
- ▶ Increases with eccentricity
- ▶ and stimulus size
- ▶ It is possible to detect flicker even at 2kHz
 - ▶ For saccadic eye motion

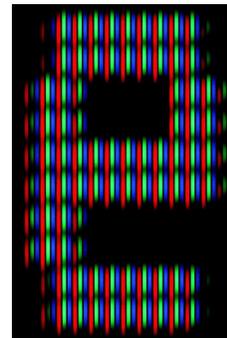

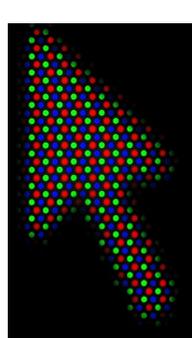

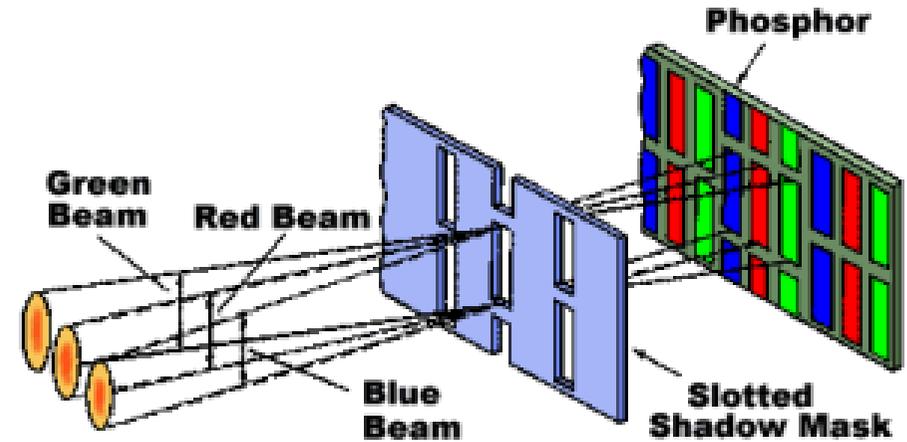

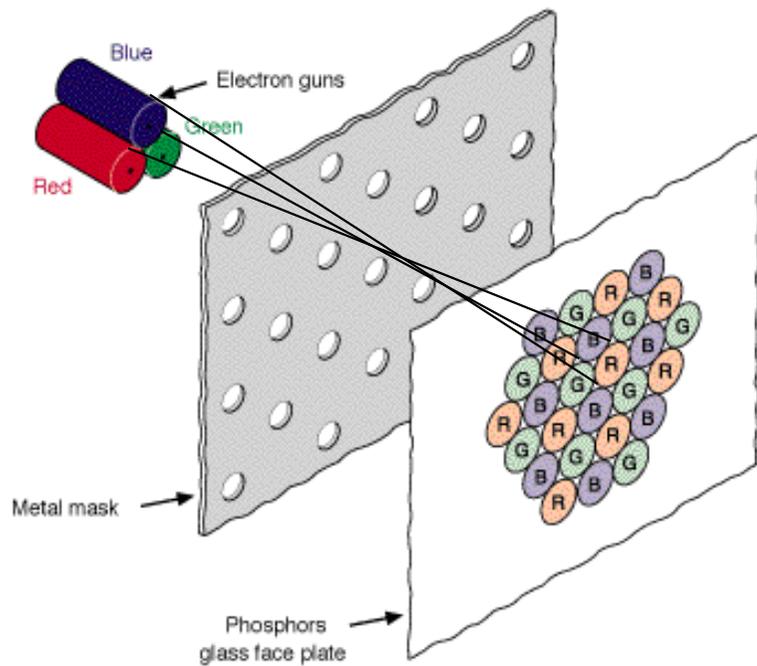

[Hartmann et al. 1979]

[Texas Instruments](#)

- ▶ 2-D array of mirrors
- ▶ Truly digital pixels
- ▶ Grey levels via Pulse-Width Modulation

Liquid Crystal on Silicon (LCoS)

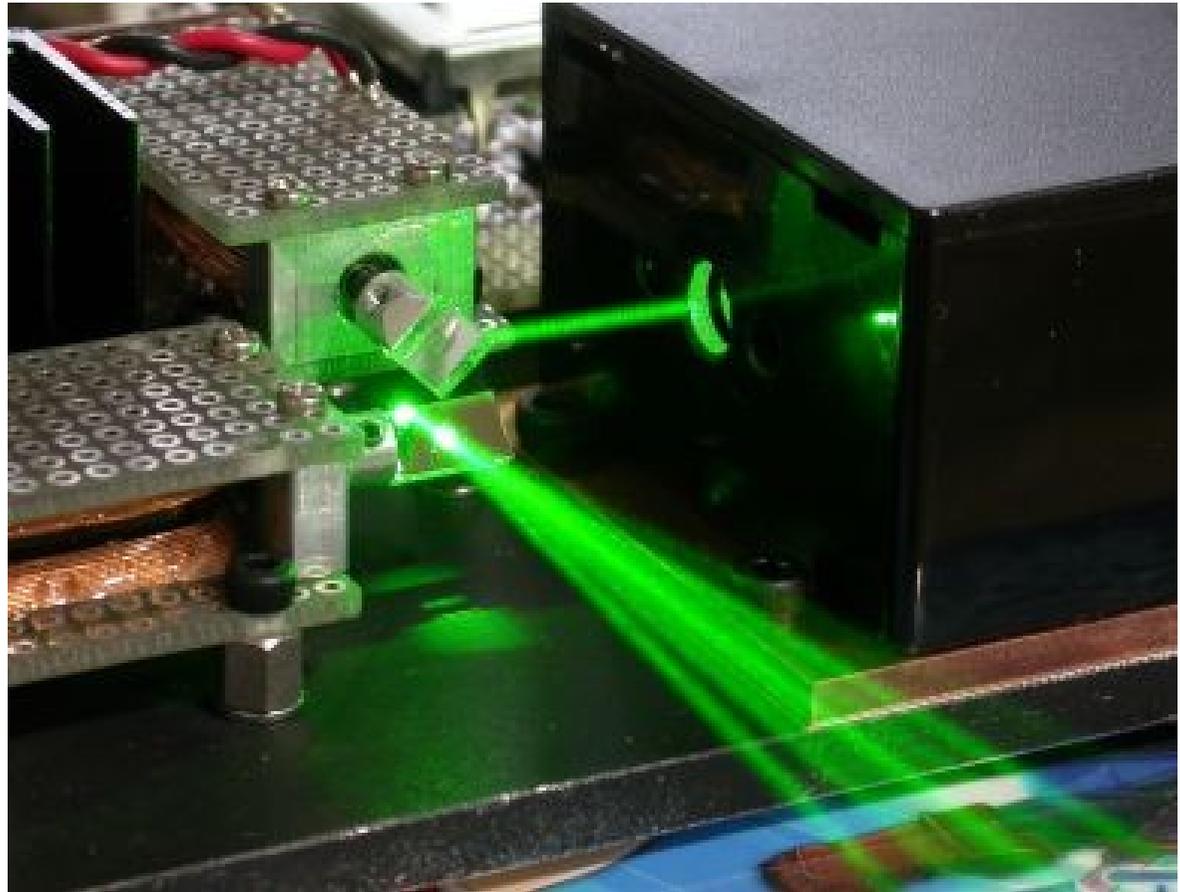

- ▶ basically a reflective LCD
- ▶ standard component in projectors and head mounted displays
- ▶ used e.g. in Google Glass

Scanning Laser Projector

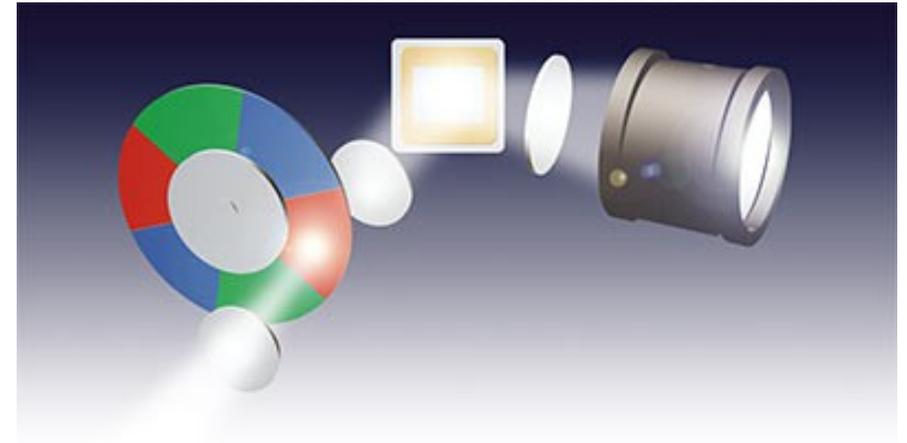

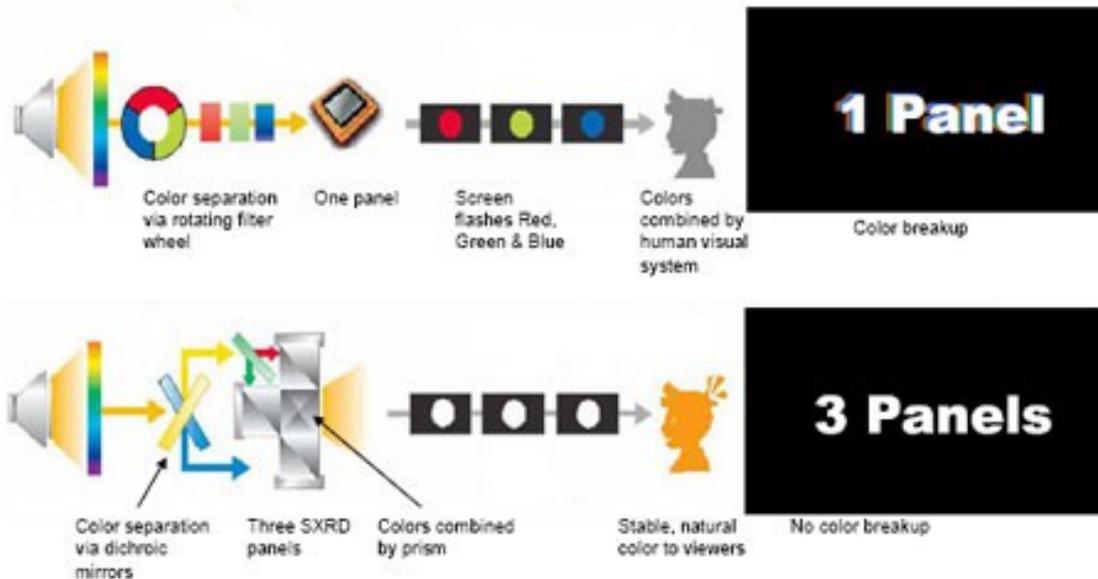

- ▶ maximum contrast
- ▶ scanning rays

- ▶ very high power lasers needed for high brightness

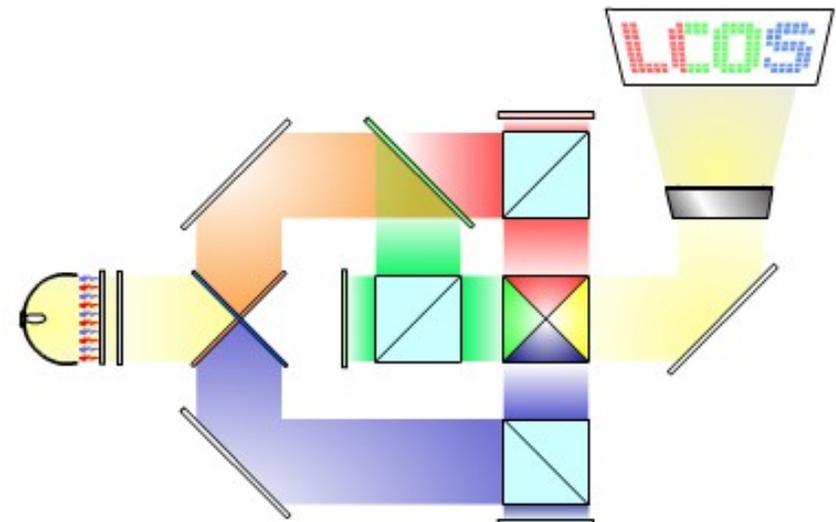

http://elm-chan.org/works/vlp/report_e.html

3-chip vs. Color Wheel Display

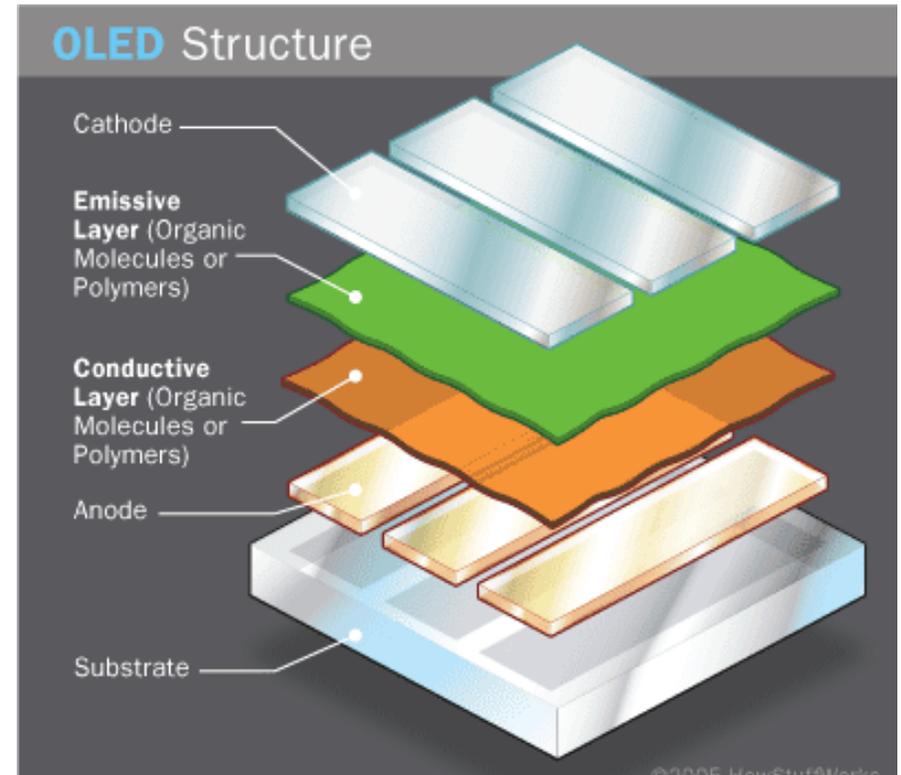

- ▶ color wheel
 - ▶ cheap
 - ▶ time sequenced colors
 - ▶ color fringes with motion/video
- ▶ 3-chip
 - ▶ complicated setup
 - ▶ no color fringes

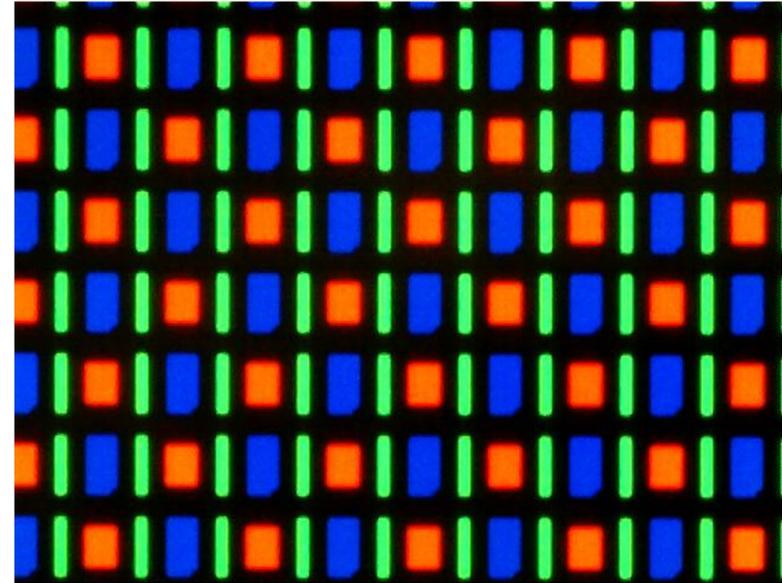

OLED

- ▶ based on electrophosphorescence
 - ▶ large viewing angle
 - ▶ the power consumption varies with the brightness of the image
 - ▶ fast (< 1 microsec)
 - ▶ arbitrary sizes
-
- ▶ life-span can be short
 - ▶ Worst for blue OLEDs

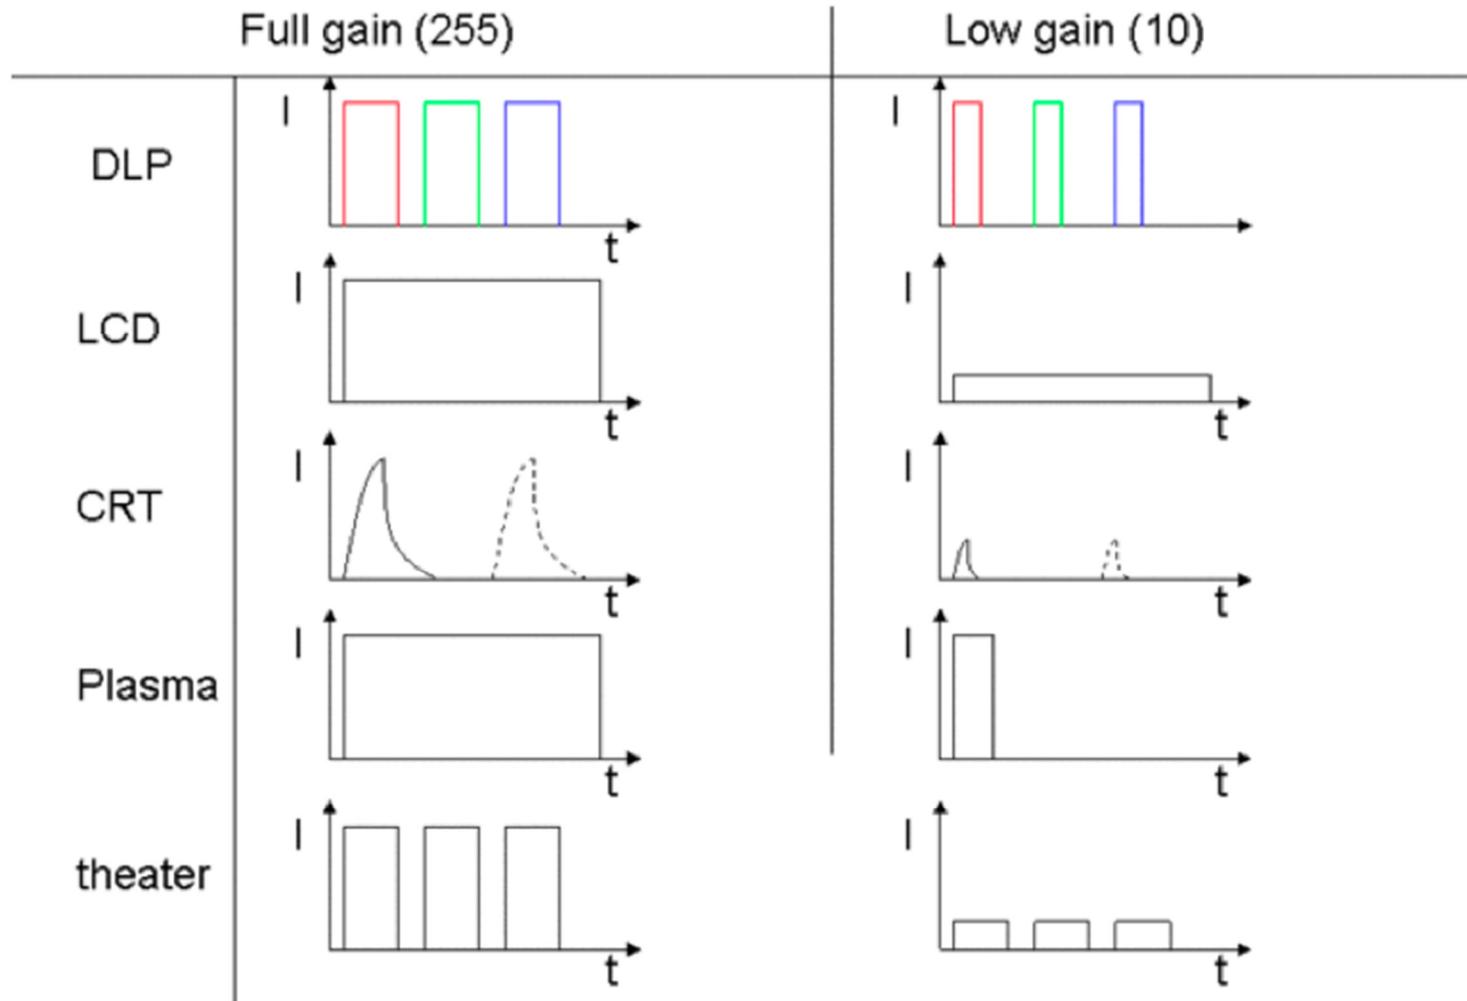

Active matrix OLED

- ▶ Commonly used in mobile phones (AMOLED)
- ▶ Very good contrast
 - ▶ But the screen more affected by glare than LCD
- ▶ But limited brightness
 - ▶ The brighter is OLED, the shorter is its live-span

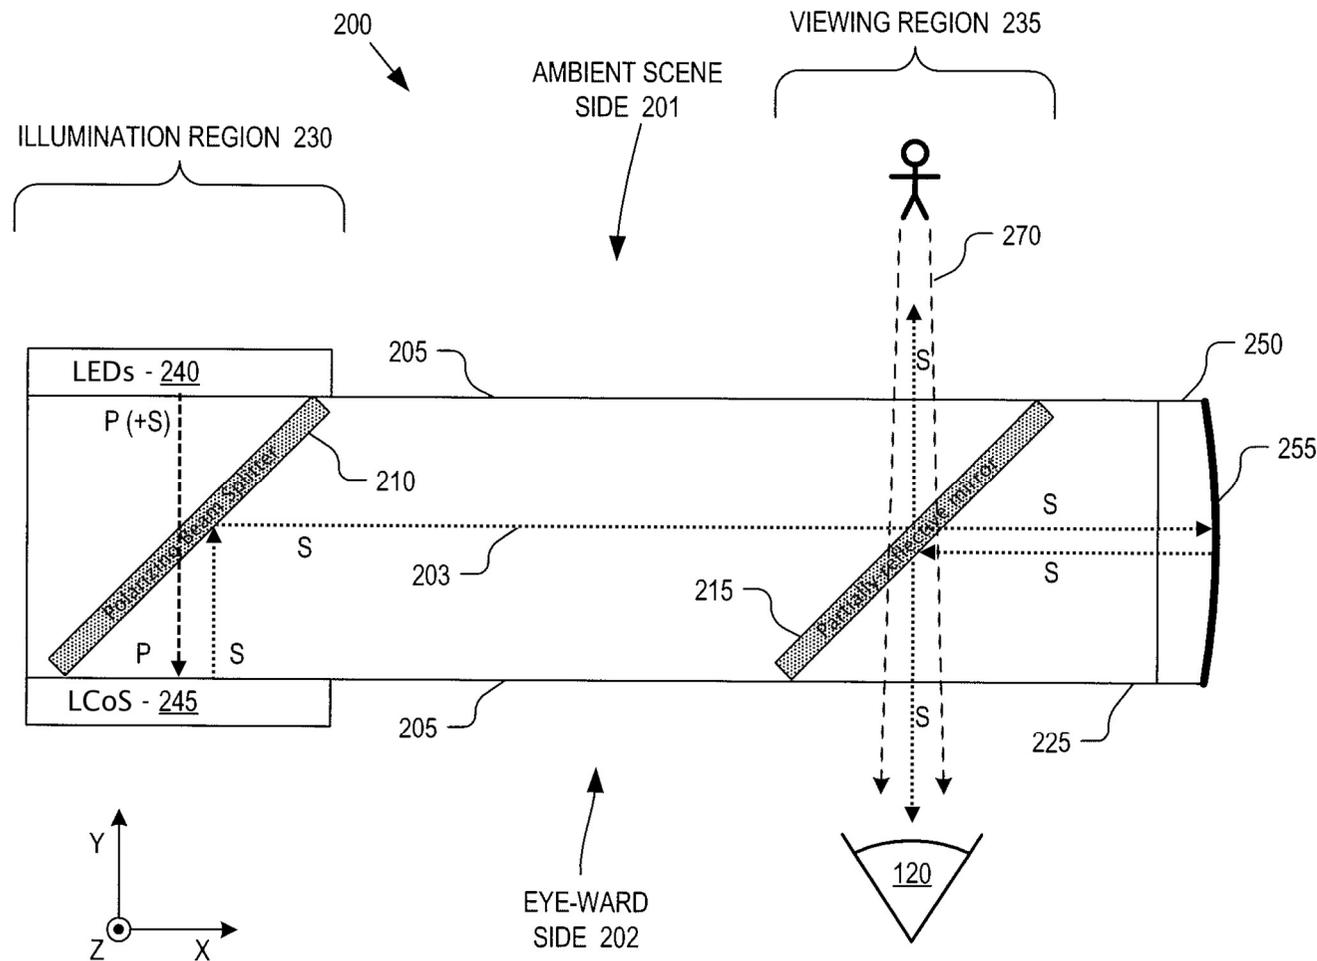

Temporal characteristic

(57) **ABSTRACT**
 A waveguide has a front and a rear surface, the waveguide for a display system and arranged to guide light from a light engine onto an eye of a user to make an image visible to the user, the light guided through the waveguide by reflection at the front and rear surfaces. A first portion of the front or rear surface has a structure which causes light to change phase upon reflection from the first portion by a first amount. A second portion of the same surface has a different structure which causes light to change phase upon reflection from the second portion by a second amount different from the first amount. The first portion is offset from the second portion by a distance which substantially matches the difference between the second amount and the first amount.

Prototype HDR display (2004)

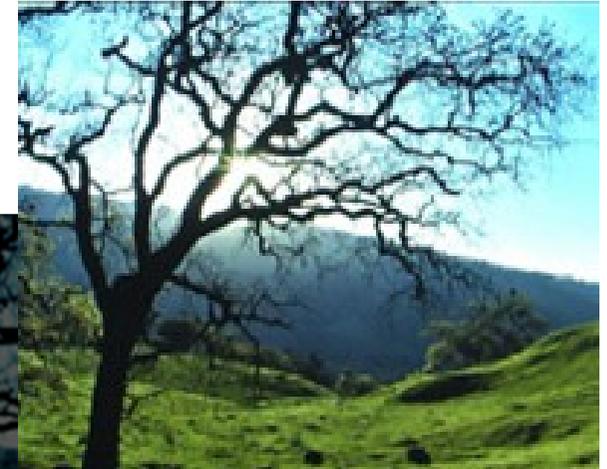

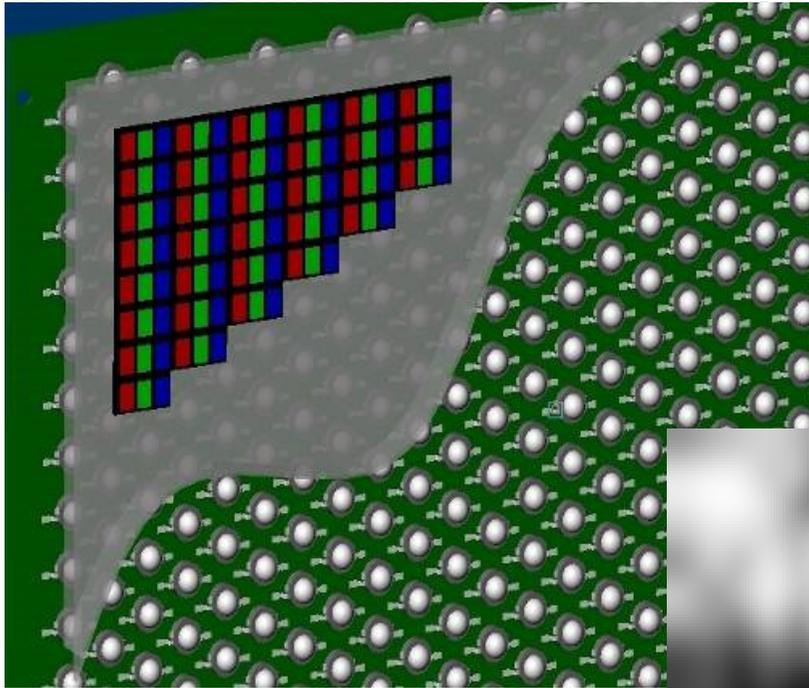

From [Seetzen et al. SIGGRAPH 2004]

Cambridge experimental HDR display

- ▶ 35,000 cd/m² peak luminance
- ▶ 0.01 cd/m² black level
- ▶ LCD resolution: 2048x1536
- ▶ Backlight (DLP) resolution: 1024x768
- ▶ Geometric-calibration with a DSLR camera
- ▶ Display uniformity compensation
- ▶ Bit-depth of DLP and LCD extended to 10 bits using spatio-temporal dithering

Modern HDR displays

- Modulated LED array
- Conventional LCD
- Image compensation

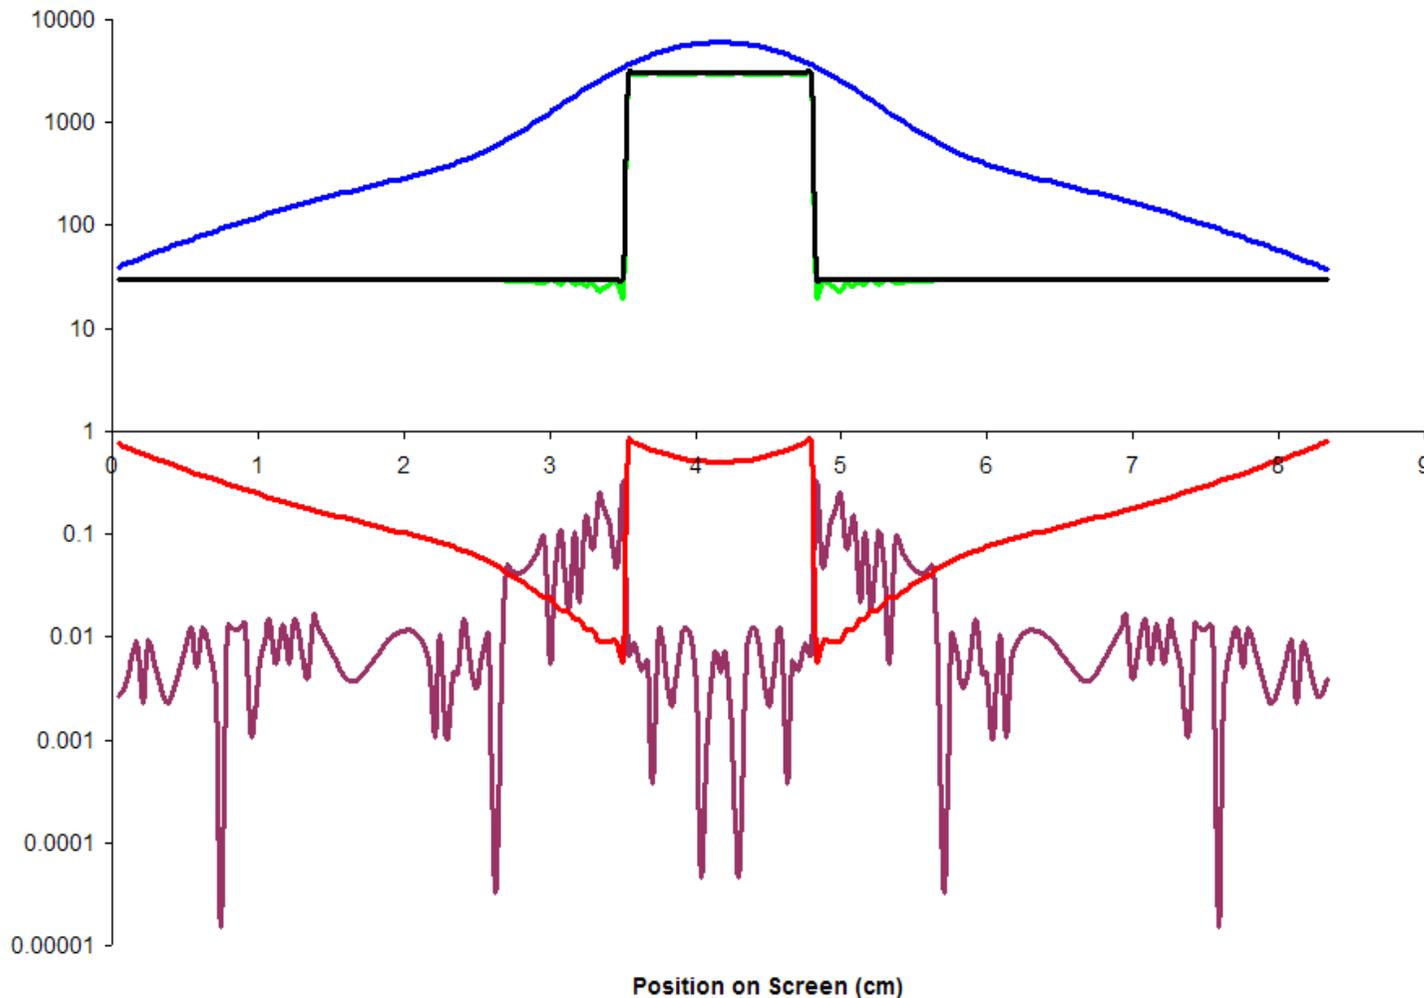

Low resolution LED Array \times High resolution Colour Image = High Dynamic Range Display

HDR Display

- ▶ **Two spatial modulators**
 - ▶ 1st modulator contrast 1000:1
 - ▶ 2nd modulator contrast 1000:1
 - ▶ Combined contrast 1000,000:1
- ▶ **Idea: Replace constant backlight of LCD panels with an array of LEDs**
 - ▶ Very few (about 1000) LEDs sufficient
 - ▶ Every LED intensity can be set individually
 - ▶ Very flat form factor (fits in standard LCD housing)
- ▶ **Issue:**
 - ▶ LEDs larger than LCD pixels
 - ▶ This limits maximum local contrast

Veiling Luminance

Advanced Graphics and Image Processing - Lecture notes

Rafał Mantiuk

Lent term 2018/19

1 Contrast- and gradient-based methods

Many problems in image processing are easier to solve or produce better results if operations are not performed directly on image pixel values but on differences between pixels. Instead of altering pixels, we can transform an image into gradient field and then edit the values in the gradient field. Once we are done with editing, we need to reconstruct an image from the modified gradient field.

A few examples of gradient-based methods are shown in Figures 1 and 2.

In one common case such differences between pixels represent gradients: for image I , a gradient at a pixel location (x, y) is computed as:

$$\nabla I_{x,y} = \begin{bmatrix} I_{x+1,y} - I_{x,y} \\ I_{x,y+1} - I_{x,y} \end{bmatrix}. \quad (1)$$

The equation above is obviously a discrete approximation of a gradient, as we are dealing with discrete pixel values rather than a continuous function. This particular approximation is called forward difference, as we take the difference between the next and current pixel. Other choices include backward differences (current minus previous pixel) or central differences (next minus previous pixel).

Once a gradient field is computed, we can start modifying it. Usually better effects are achieved if the magnitude of gradients is modified and the orientation of each gradient remains unchanged. This can be achieved by

(a) Original image

(b) Details enhanced

(c) Cartoonized image

Figure 1: Two examples of gradient-based processing. Texture details in the original image were enhanced to produce the result shown in (b). Contrast was removed everywhere except at the edges to produce a cartoonized image in (c).

multiplying gradients by the gradient editing function $f()$:

$$G_{x,y} = \nabla I_{x,y} \cdot \frac{f(\|\nabla I_{x,y}\|)}{\|\nabla I_{x,y}\|} \quad (2)$$

where $\|\cdot\|$ operator computes the magnitude (norm) of the gradient.

We try to reconstruct pixel values, which would result in a gradient field that is the closest to our modified gradient field $G = [G^{(x)} \ G^{(y)}]'$. In particular, we can try to minimize the squared differences between gradients in actual image and modified gradients:

$$\arg \min_I \sum_{x,y} \left[(I_{x+1,y} - I_{x,y} - G_{x,y}^{(x)})^2 + (I_{x,y+1} - I_{x,y} - G_{x,y}^{(y)})^2 \right], \quad (3)$$

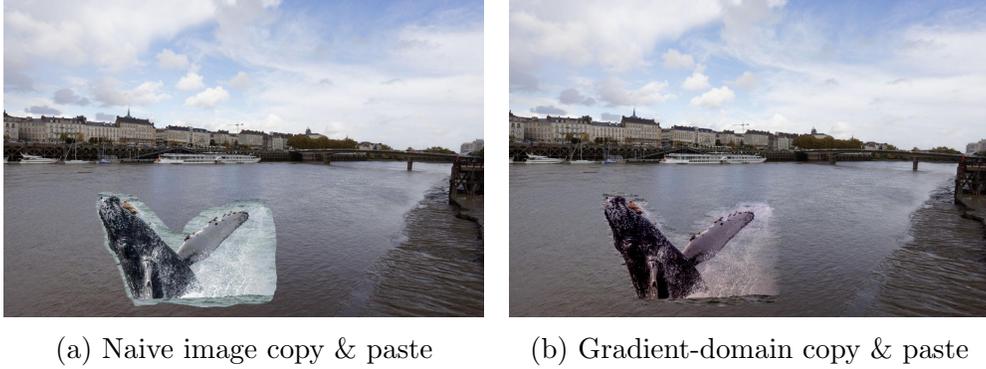

Figure 2: Comparison of naive and gradient domain image copy & paste.

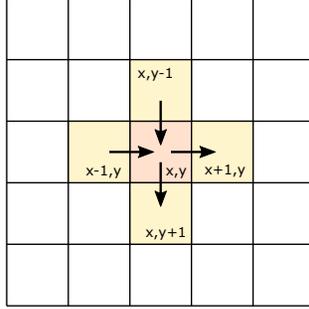

Figure 3: When using forward-differences, a pixel with the coordinates (x, y) is referred to in at most four partial derivatives, two along x -axis and two along y -axis.

where the summation is over the entire image. To minimize the function above, we need to equate its partial derivatives to 0. As we optimize for pixel values, we need to compute partial derivatives with respect to $I_{x,y}$. Fortunately, most terms in the sum will become 0 after differentiation, as they do not contain the differentiated variable $I_{x,y}$. For a given pixel (x, y) , we need to consider only 4 partial derivatives: two belonging to the pixel (x, y) , x -derivative for the pixel on the left $(x - 1, y)$ and y -derivative for the pixel in the top $(x, y - 1)$, as shown in Figure 3. This gives us:

$$\frac{\delta F}{\delta I_{x,y}} = -2(I_{x+1,y} - I_{x,y} - G_{x,y}^{(x)}) - 2(I_{x,y+1} - I_{x,y} - G_{x,y}^{(y)}) + \quad (4)$$

$$2(I_{x,y} - I_{x-1,y} - G_{x-1,y}^{(x)}) + 2(I_{x,y} - I_{x,y-1} - G_{x,y-1}^{(y)}). \quad (5)$$

After rearranging the terms and equating $\frac{\delta F}{\delta I_{x,y}}$ to 0, we get:

$$I_{x-1,y} + I_{x+1,y} + I_{x,y-1} + I_{x,y+1} - 4I_{x,y} = G_{x,y}^{(x)} - G_{x-1,y}^{(x)} + G_{x,y}^{(y)} - G_{x,y-1}^{(y)}. \quad (6)$$

In these few steps we derived a discrete Poisson equation, which can be found in many engineering problems. The Poisson equation is often written as:

$$\nabla^2 I = \text{div}G, \quad (7)$$

where $\nabla^2 I$ is the discrete Laplace operator:

$$\nabla^2 I_{x,y} = I_{x-1,y} + I_{x+1,y} + I_{x,y-1} + I_{x,y+1} - 4I_{x,y}, \quad (8)$$

and $\text{div}G$ is the divergence of the vector field:

$$\text{div}G_{x,y} = G_{x,y}^{(x)} - G_{x-1,y}^{(x)} + G_{x,y}^{(y)} - G_{x,y-1}^{(y)}. \quad (9)$$

We can also write the equation using discrete convolution operators:

$$I * \begin{bmatrix} 0 & 1 & 0 \\ 1 & -4 & 1 \\ 0 & 1 & 0 \end{bmatrix} = G^{(x)} * \begin{bmatrix} -1 & 1 & 0 \end{bmatrix} + G^{(y)} * \begin{bmatrix} -1 \\ 1 \\ 0 \end{bmatrix}. \quad (10)$$

Note that the convolution flips the order of elements in the kernel, thus the row and column vectors on the right hand side are also flipped.

When equation 6 is satisfied for every pixel, it forms a system of linear equations:

$$A \cdot \begin{bmatrix} I_{1,1} \\ I_{2,1} \\ \dots \\ I_{N,M} \end{bmatrix} = b \quad (11)$$

Here we represent an image as a very large column vector, in which image pixels are stacked column-after-column (in an equivalent manner they can be stacked row-after-row). Every row of matrix A contains the Laplace operator for a corresponding pixel. But the matrix also needs to account for the boundary conditions, that is handle pixels that are at the image edge and therefore do not contain neighbour on one of the sides. Matrix A for a tiny

3x3 image looks like this:

$$A = \begin{bmatrix} -2 & 1 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 1 & -3 & 1 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & -2 & 0 & 0 & 1 & 0 & 0 & 0 \\ 1 & 0 & 0 & -3 & 1 & 0 & 1 & 0 & 0 \\ 0 & 1 & 0 & 1 & -4 & 1 & 0 & 1 & 0 \\ 0 & 0 & 1 & 0 & 1 & -3 & 0 & 0 & 1 \\ 0 & 0 & 0 & 1 & 0 & 0 & -2 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 1 & -3 & 1 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 1 & -2 \end{bmatrix} \quad (12)$$

Obviously, the matrix is enormous for normal size images. However, most matrix elements are 0, so it can be easily stored using a sparse matrix representation. Note that only the pixel in the center of the image (5th row) contains the full Laplace operator; all other pixels are missing neighbours so the operator is adjusted accordingly. Accounting for all boundary cases is probably the most difficult and error-prone part in formulating gradient-field reconstruction problem. The column vector b corresponds to the right hand side of equation 6.

2 Solving linear system

There is a large number of methods and software libraries, which can solve a sparse linear problem given in Equation 11. The Poisson equation is typically solved using multi-grid methods, which iteratively update the solution at different scales. Those, however, are rather difficult to implement and tailored to one particular shape of a matrix. Alternatively, the solution can be readily found after transformation to the frequency domain (discrete cosine transform). However, such a method does not allow introducing weights, importance of which will be discussed in the next section. Finally, conjugate gradient and biconjugate gradient [1, sec. 2.7] methods provide a fast-converging iterative method for solving sparse systems, which can be very memory efficient. Those methods require providing only a way to compute multiplication of the matrix A and its transpose with an arbitrary vector. Such operation can be realized in an arbitrary way without the need to store the sparse matrix (which can be very large even if it is sparse). The conjugate gradient requires fewer operations than the biconjugate gradient method, but

(a) Uniform weights

(b) Higher weights at low contrast

Figure 4: The solution of gradient field reconstruction often contain "pinching" artefacts, such as shown in figure (a). The artefacts can be avoided if small gradient magnitudes are weighted more than large magnitudes.

it should be used only with positive definite matrices. Matrix A is not positive definite so in principle the biconjugate gradient method should be used. However, in practice, conjugate gradient method converges equally well.

3 Weighted reconstruction

An image resulting from solving Equation 11 often contains undesirable "pinching" artefacts, such as those shown in Figure 4a. Those artefacts are inherent to the nature of gradient field reconstruction — the solution is just the best approximation of the desired gradient field but it hardly ever exactly matches the desired gradient field. As we minimize squared differences, tiny inaccuracies for many pixels introduce less error than large inaccuracies for few pixels. This in turn introduces smooth gradients in the areas, where the desired gradient field is inconsistent (cannot form an image). Such gradients produce "pinching" artefacts.

The problem is that the error in reconstructed gradients is penalized the same regardless of whether the value of the gradient is small or large. This is opposite to how the visual system perceives differences in color values: we are more likely to spot tiny difference between two similar pixel values than the same tiny difference between two very different pixel values. We could account for that effect by introducing some form of non-linear metric, however, that would make our problem non-linear and non-linear problems are in general much slower to solve. However, the same can be achieved by introducing weights to our objective function:

$$\arg \min_I \sum_{x,y} \left[w_{x,y}^{(x)} (I_{x+1,y} - I_{x,y} - G_{x,y}^{(x)})^2 + w_{x,y}^{(y)} (I_{x,y+1} - I_{x,y} - G_{x,y}^{(y)})^2 \right], \quad (13)$$

where $w_{x,y}^{(x)}$ and $w_{x,y}^{(y)}$ are the weights or importance we assign to each gradient, for horizontal and vertical partial derivatives respectively. Usually the weights are kept the same for both orientations, i.e. $w_{x,y}^{(x)} = w_{x,y}^{(y)}$. To account for the contrast perception of the visual system, we need to assign a higher weight to small gradient magnitudes. For example, we could use the weight:

$$w_{x,y}^{(x)} = w_{x,y}^{(y)} = \frac{1}{\|G_{x,y}\| + \epsilon} \quad (14)$$

where $\|G_{x,y}\|$ is the magnitude of the desired (target) gradient at pixel (x, y) and ϵ is a small constant (0.0001), which prevents division by 0.

4 Matrix notation

We could follow the same procedure as in the previous section and differentiate Equation 13 to find the linear system that minimizes our objective. However, the process starts to be tedious and error-prone. As the objective functions gets more and more complex, it is worth switching to the matrix notation. Let us consider first our original problem without the weights $w_{x,y}$, which we will add later. Equation 3 in the matrix notation can be written as:

$$\arg \min_I \left\| \begin{bmatrix} \nabla_x \\ \nabla_y \end{bmatrix} I - \begin{bmatrix} G^{(x)} \\ G^{(y)} \end{bmatrix} \right\|^2. \quad (15)$$

In the equation I , $G^{(x)}$ and $G^{(y)}$ are stacked column vectors, representing columns of the resulting image or desired gradient field. The square brackets

denote vertical concatenation of the matrices or vectors. Operator $\|\cdot\|^2$ is the L_2 -norm, which squares and sums the elements of the resulting column vector. ∇_x and ∇_y are differential operators, which are represented as $N \times N$ matrices, where N is the number of pixels. Each row of those sparse matrices tells us which pixels need to be subtracted from one another to compute forward gradients along horizontal and vertical directions. For a tiny 3×3 pixel image those operators are:

$$\nabla_x = \begin{bmatrix} -1 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & -1 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & -1 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & -1 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix} \quad (16)$$

$$\nabla_y = \begin{bmatrix} -1 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & -1 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & -1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & -1 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & -1 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix} \quad (17)$$

Note that the rows contain all zeros for pixels on the boundary, for which no gradient can be computed: the last column of pixels for ∇_x and the last row of pixels for ∇_y .

Equation 15 is in the format $\|Ax - b\|^2$, which can be directly solved by some sparse matrix libraries, such as `SciPy.sparse` or the `"\"` operator in matlab Matlab. However, to reduce the size of the sparse matrix and to speed-up computation, it is worth taking one more step and transform the least-square optimization into a linear problem. For overdetermined systems, such as ours, the solution of the optimization problem:

$$\arg \min_x \|Ax - b\|^2 \quad (18)$$

can be found by solving a linear system:

$$A'Ax = A'b. \quad (19)$$

Note that $'$ denotes a matrix transpose and $A'A$ is a square matrix. If we replace A and b with the corresponding operators and gradient values from our problem, we get the following linear system:

$$\begin{bmatrix} \nabla'_x & \nabla'_y \end{bmatrix} \begin{bmatrix} \nabla_x \\ \nabla_y \end{bmatrix} I = \begin{bmatrix} \nabla'_x & \nabla'_y \end{bmatrix} \begin{bmatrix} G^{(x)} \\ G^{(y)} \end{bmatrix}, \quad (20)$$

which, after multiplying stacked matrices, gives us:

$$(\nabla'_x \nabla_x + \nabla'_y \nabla_y) I = \nabla'_x G^{(x)} + \nabla'_y G^{(y)}. \quad (21)$$

Weights can be added to such a system by inserting a sparse diagonal matrix W . For simplicity we use the same weights for vertical and horizontal derivatives:

$$(\nabla'_x W \nabla_x + \nabla'_y W \nabla_y) I = \nabla'_x W G^{(x)} + \nabla'_y W G^{(y)}. \quad (22)$$

The above operations can be performed using a sparse matrix library (or SciPy/Matlab), thus saving us effort of computing operators by hand.

There is still one problem remaining: our equation does not have a unique solution. This is because the target gradient field contains relative information about differences between pixels, but it does not say what the absolute value of the pixels should be. For that reason, we need to constrain the absolute value, for example by ensuring that a value of a first reconstructed pixel is the same as in the source image (I_{src}):

$$\begin{bmatrix} 1 & 0 & \dots & 0 \end{bmatrix} I = I_{src}(1, 1). \quad (23)$$

If we denote the vector on the left-hand side of the equation as C , the final linear problem can be written as:

$$(\nabla'_x W \nabla_x + \nabla'_y W \nabla_y + C' C) I = \nabla'_x W G^{(x)} + \nabla'_y W G^{(y)} + C' I_{src}(1, 1). \quad (24)$$

The resulting equation can be solved using a sparse solver in Python or Matlab.

1 Light field rendering using homographic transformation

This section explains how to render a light field for a novel view position using a parametrization with a focal plane. The method is explained on a rather high level in [1]. These notes are meant to provide a practical guide on how to perform the required calculations and in particular how to find a homographic transformation between the virtual and array cameras.

The scenario and selected symbols are illustrated in Figure 1. We want to render our light field "as seen" by camera K . We have N images captured by N cameras in the array (only 4 shown in the figure), all of which have their apertures on the camera array plane C . We further assume that our array cameras are pin-hole cameras to simplify the explanation. The novel view is rendered assuming focal plane F . The focal plane has a similar function as the focus distance in a regular camera: objects on the focal plane will be rendered sharp, while objects that are in front or behind that plane will appear blurry (in practice they will appear ghosted because of the limited number of cameras). The focal plane F does not need to be parallel to the camera plane; it can be tilted, unlike in a traditional camera with a regular lens. Because we have a limited number of cameras, we need to use reconstruction functions A_0, \dots, A_1 (only two shown) for each camera. The functions shown contain the weights in the range 0-1 that are used to interpolate between two neighboring views.

To intuitively understand how light field rendering is performed, imagine the following hypothetical scenario. Each camera in the array captures the

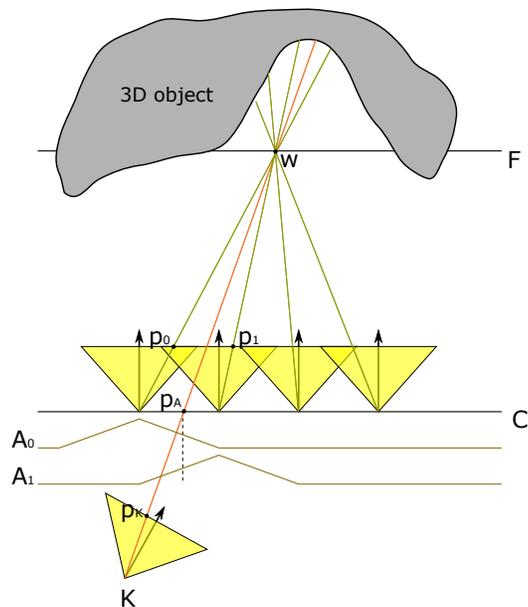

Figure 1: Light field rendering for the novel view represented by camera K . The pixels P_K in the rendered image is the weighted average of the pixels values p_1, \dots, p_N from the images captured by the camera array.

image of the scene. Then, all objects in the scene are removed and you put a large projection screen where the focal plane F should be. Then, you swap all cameras for projectors, which project the captured images on the projection screen F . Finally, you put a new camera K at the desired location and capture the image of the projection screen. The projection screen (focal plane) is needed to form an image. Ideally, to obtain a sharp image, we would like to project the camera array images on a geometry. However, such a geometry is not readily available when capturing scenes with a camera array. In this situation a single plane is often a good-enough proxy, which has its analogy in physical cameras (focal distance). More advanced light field rendering methods attempt to reconstruct a more accurate proxy geometry using multi-view stereo algorithms and then project camera images on that geometry [3].

This simplified scenario misses one step, which is modulating each projected image by the reconstruction function A , as such modulation has no physical counterpart. However, this scenario should give you a good idea what operations need to be performed in order to render a light field from a

Algorithm 1: Light field rendering algorithm

novel view position.

Now let us see how we can turn such a high-level explanation into a practical algorithm. One way to render a light field is shown in Algorithm 1. The algorithm iterates over all pixels in the rendered image, then for each pixel it iterates over all cameras in the array. The resulting image is the weighted average of the camera images that are warped using homographic transformations. The weights are determined by the reconstruction functions A_i . The algorithm is straightforward, except for the mapping from pixel coordinates in the novel view \mathbf{p}_K to coordinates in each camera image \mathbf{p}_i and the coordinates on the aperture plane \mathbf{p}_A . The following paragraphs explain how to find such transformations.

1.1 Homographic transformation between the virtual and array cameras

The text below assumes that you are familiar with homogeneous coordinates and geometric transformations, both commonly used in computer graphics and computer vision. If these topics are still unclear, refer to Section 2.1 in [4] (this book is available online) or Chapter 6 in [2].

We assume that we know the position and pose of each camera in the

array, so that homogeneous 3D coordinates of a point in the 3D world coordinate space w can be mapped to the 2D pixel coordinates p_i of camera i :

$$\mathbf{p}_i = \mathbf{K} \mathbf{P} \mathbf{V}_i \mathbf{w}. \quad (1)$$

where \mathbf{V} is the view transformation, \mathbf{P} is the projection matrix and \mathbf{K} is the intrinsic camera matrix. Note that we will use bold lower case symbols to denote vectors, uppercase bold symbols for matrices and a regular font for scalars. The operation is easier to understand if the coordinates and matrices are expanded:

$$\begin{bmatrix} x_i \\ y_i \\ w_i \end{bmatrix} = \begin{bmatrix} f_x & 0 & c_x \\ 0 & f_y & c_y \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \end{bmatrix} \begin{bmatrix} v_{11} & v_{12} & v_{13} & v_{14} \\ v_{21} & v_{22} & v_{23} & v_{24} \\ v_{31} & v_{32} & v_{33} & v_{34} \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} X \\ Y \\ Z \\ 1 \end{bmatrix}. \quad (2)$$

The view matrix \mathbf{V} translates and rotates the 3D coordinates of the 3D point \mathbf{w} so that the origin of the new coordinate system is at the camera centre, and camera's optical axis is aligned with the z-axis (as the view matrix in computer graphics). This matrix can be computed using a *LookAt* function, often available in graphics matrix libraries.

The projection matrix \mathbf{P} may look like an odd version of an identity matrix, but it actually drops one dimension (projects from 3D to 2D) and copies the value of Z coordinate into the additional homogeneous coordinate w_i . Note that to compute Cartesian coordinates of the point from the homogeneous coordinates, we divide x_i/w_i and y_i/w_i . As w_i is now equal to the depth in the camera coordinates, this operation is equivalent to a perspective projection (you can refer to slides 88–92 in the Introduction to Graphics Course).

The intrinsic camera matrix \mathbf{K} maps the projected 3D coordinates into pixel coordinates. f_x and f_y are focal lengths and c_x and c_y are the coordinates of optical center expressed in pixel coordinates. We assume that the intrinsic matrix is the same for all the cameras in the array.

Besides having all matrices for all cameras in the array, we also have a similar transformation for our virtual camera K , which represents the currently rendered view:

$$\mathbf{p}_K = \mathbf{K}_K \mathbf{P} \mathbf{V}_K \mathbf{w}. \quad (3)$$

Our first task is to find transformation matrices that could transform from pixel coordinates \mathbf{p}_K in the virtual camera image into pixel coordinates \mathbf{p}_i

for each camera i . This is normally achieved by inverting the transformation matrix for the novel view and combining it with the camera array transformation. However, the problem is that the product of $\mathbf{K}_K \mathbf{P} \mathbf{V}_K$ is not a square matrix that can be inverted — it is missing one dimension. The dimension is missing because we are projecting from 3D to 2D and one dimension (depth) is lost.

Therefore, to map both coordinates, we need to reintroduce missing information. This is achieved by assuming that the 3D point lies on the focal plane F . Note that the plane equation can be expressed as $\mathbf{N} \cdot (\mathbf{w} - \mathbf{w}_F) = 0$, where \mathbf{N} is the plane normal, and \mathbf{w}_F specifies the position of the plane in the 3D space. Operator \cdot is the dot product. If the homogeneous coordinates of the point \mathbf{w} are $[X \ Y \ Z \ 1]$, the plane equation can be expressed as

$$d = [n_x \ n_y \ n_z \ -\mathbf{N} \cdot \mathbf{w}_F] \begin{bmatrix} X \\ Y \\ Z \\ 1 \end{bmatrix}, \quad (4)$$

where d is the distance to the plane and $\mathbf{N} = [n_x \ n_y \ n_z]$. We can introduce the plane equation into the projection matrix from Equation 2:

$$\begin{bmatrix} x_i \\ y_i \\ d_i \\ w_i \end{bmatrix} = \begin{bmatrix} f_x & 0 & 0 & c_x \\ 0 & f_y & 0 & c_y \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ n_x^{(c)} & n_y^{(c)} & n_z^{(c)} & -\mathbf{N}^{(c)} \cdot \mathbf{w}_F^{(c)} \\ 0 & 0 & 1 & 0 \end{bmatrix} \begin{bmatrix} v_{11} & v_{12} & v_{13} & v_{14} \\ v_{21} & v_{22} & v_{23} & v_{24} \\ v_{31} & v_{32} & v_{33} & v_{34} \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} X \\ Y \\ Z \\ 1 \end{bmatrix}. \quad (5)$$

The product of the matrices in above is a full 4×4 transformation matrix, which is not rank-deficient and can be inverted. Note that the pixel coordinates \mathbf{p}_K and \mathbf{p}_i now have an extra dimension d , which should be set to 0 (because we constrain 3D point w to lie on the focal plane).

It should be noted that the normal and the point in the plane equation have superscript (c) , which denotes that the plane is given in the *camera* coordinate system, rather than in the world coordinate system. This is because the point $[X \ Y \ Z \ 1]$ is transformed from the world to the camera coordinates by the view matrix \mathbf{V}_i before it is multiplied by our modified projection matrix. This could be a desired behavior for the virtual camera, for example if we want the focal plane to follow the camera and be perpendicular to the camera's optical axis. But, if we simply want to specify the focal plane in the

world coordinates, we have two options: either replace the third row in the final matrix (obtained after multiplying the three matrices in Equation 5) with our plane equation in the world coordinate system; or to transform the plane to the camera coordinates:

$$\mathbf{w}_F^{(c)} = \mathbf{V}_i \mathbf{w}_F \quad (6)$$

and

$$\mathbf{N}^{(c)} = \bar{\mathbf{V}}_i \mathbf{N}. \quad (7)$$

$\bar{\mathbf{V}}_i$ is the "normal" or direction transformation for the view matrix \mathbf{V}_i , which rotates the normal vector but it does not translate it. It is obtained by setting to zero the translation coefficients w_{14} , w_{24} , and w_{34} .

Now let us find the final mapping from the virtual camera coordinates \mathbf{p}_K to the array camera coordinates $\hat{\mathbf{p}}_i$. We will denote the extended coordinates (with extra d) in Equation 5 as $\mathbf{p}_{\hat{K}}$ and $\hat{\mathbf{p}}_i$. We will also denote our new projection and intrinsic matrices in Equation 5 as $\hat{\mathbf{P}}$ and $\hat{\mathbf{K}}$. Given that, the mapping from \mathbf{p}_K to \mathbf{p}_i can be expressed as:

$$\hat{\mathbf{p}}_i = \hat{\mathbf{K}}_i \hat{\mathbf{P}} \mathbf{V}_i \mathbf{V}_K^{-1} \hat{\mathbf{P}}^{-1} \hat{\mathbf{K}}_K^{-1} \mathbf{p}_K. \quad (8)$$

The position on the aperture plane \mathbf{w}_A can be readily found from:

$$\mathbf{w}_A = \mathbf{V}_K^{-1} \hat{\mathbf{P}}_A^{-1} \hat{\mathbf{K}}_K^{-1} \mathbf{p}_K, \quad (9)$$

where the projection matrix $\hat{\mathbf{P}}_A$ is modified to include the plane equation of the aperture plane, the same way as done in Equation 5.

1.2 Reconstruction functions

The choice of the reconstruction function A_i will determine how images from different cameras are mixed together. The functions shown in Figure 1 will perform bilinear-interpolation between the views. Although this could be a rational choice, it will result in ghosting for the parts of the scene that are further away from the focal plane F . Another choice is to simulate a wide-aperture camera and include all cameras in the generated view (set $A_i = 1$). This will produce an image with a very shallow depth of field. Another possibility is to use the nearest-neighbor strategy and a box-shaped reconstruction filter (the width of the boxes being equal to the distance between the cameras). This approach will avoid ghosting but will cause the views

to jump sharply as the virtual camera moves over the scene. It is worth experimenting with different reconstruction strategies to choose the best for a given application but also for the given angular resolution of the light field (number of views).
