

## Randomised Algorithms

Lecture 10: Approximation Algorithms: Set-Cover and MAX-CNF

Thomas Sauerwald (tms41@cam.ac.uk)

Lent 2025

## Outline

Weighted Set Cover

MAX-CNF

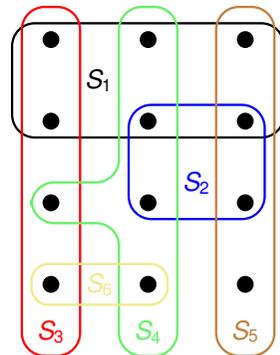

## The Weighted Set-Cover Problem

Set Cover Problem

- Given: set  $X$ ,  $|X| = n$ , a family of subsets  $\mathcal{F}$ , and cost function  $c : \mathcal{F} \rightarrow \mathbb{R}^+$
- Goal: Find a minimum-cost subset  $\mathcal{C} \subseteq \mathcal{F}$

Sum over the costs of all sets in  $\mathcal{C}$

$$\text{s.t. } X = \bigcup_{S \in \mathcal{C}} S.$$

|         |       |       |       |       |       |
|---------|-------|-------|-------|-------|-------|
| $S_1$   | $S_2$ | $S_3$ | $S_4$ | $S_5$ | $S_6$ |
| $c : 2$ | $3$   | $3$   | $5$   | $1$   | $2$   |

Remarks:

- generalisation of the weighted Vertex-Cover problem
- models resource allocation problems

## Setting up an Integer Program

**Question:** Try to formulate the integer program and linear program of the weighted SET-COVER problem (solution on next slide!)

## Setting up an Integer Program

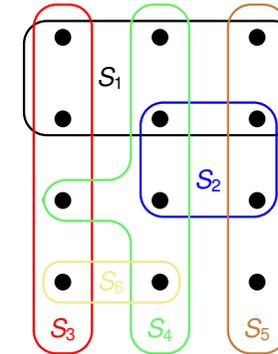

0-1 Integer Program

$$\begin{aligned} &\text{minimize} && \sum_{S \in \mathcal{F}} c(S)y(S) \\ &\text{subject to} && \sum_{S \in \mathcal{F}: x \in S} y(S) \geq 1 \quad \text{for each } x \in X \\ &&& y(S) \in \{0, 1\} \quad \text{for each } S \in \mathcal{F} \end{aligned}$$

Linear Program

$$\begin{aligned} &\text{minimize} && \sum_{S \in \mathcal{F}} c(S)y(S) \\ &\text{subject to} && \sum_{S \in \mathcal{F}: x \in S} y(S) \geq 1 \quad \text{for each } x \in X \\ &&& y(S) \in [0, 1] \quad \text{for each } S \in \mathcal{F} \end{aligned}$$

## Back to the Example

|                    | S <sub>1</sub> | S <sub>2</sub> | S <sub>3</sub> | S <sub>4</sub> | S <sub>5</sub> | S <sub>6</sub> |
|--------------------|----------------|----------------|----------------|----------------|----------------|----------------|
| c :                | 2              | 3              | 3              | 5              | 1              | 2              |
| $\bar{y}(\cdot)$ : | 1/2            | 1/2            | 1/2            | 1/2            | 1              | 1/2            |

Cost equals 8.5

The strategy employed for Vertex-Cover would take all 6 sets!

Even worse: If all  $\bar{y}$ 's were below 1/2, we would not even return a valid cover!

## Randomised Rounding

|                    | S <sub>1</sub> | S <sub>2</sub> | S <sub>3</sub> | S <sub>4</sub> | S <sub>5</sub> | S <sub>6</sub> |
|--------------------|----------------|----------------|----------------|----------------|----------------|----------------|
| c :                | 2              | 3              | 3              | 5              | 1              | 2              |
| $\bar{y}(\cdot)$ : | 1/2            | 1/2            | 1/2            | 1/2            | 1              | 1/2            |

Idea: Interpret the  $\bar{y}$ -values as probabilities for picking the respective set.

Randomised Rounding

- Let  $\mathcal{C} \subseteq \mathcal{F}$  be a random set with each set  $S$  being included independently with probability  $\bar{y}(S)$ .
- More precisely, if  $\bar{y}$  denotes the optimal solution of the LP, then we compute an integral solution  $y$  by:

$$y(S) = \begin{cases} 1 & \text{with probability } \bar{y}(S) \\ 0 & \text{otherwise.} \end{cases} \quad \text{for all } S \in \mathcal{F}.$$

- Therefore,  $\mathbf{E}[y(S)] = \bar{y}(S)$ .

## Randomised Rounding

|                    | S <sub>1</sub> | S <sub>2</sub> | S <sub>3</sub> | S <sub>4</sub> | S <sub>5</sub> | S <sub>6</sub> |
|--------------------|----------------|----------------|----------------|----------------|----------------|----------------|
| c :                | 2              | 3              | 3              | 5              | 1              | 2              |
| $\bar{y}(\cdot)$ : | 1/2            | 1/2            | 1/2            | 1/2            | 1              | 1/2            |

Idea: Interpret the  $\bar{y}$ -values as probabilities for picking the respective set.

Lemma

- The expected cost satisfies

$$\mathbf{E}[c(\mathcal{C})] = \sum_{S \in \mathcal{F}} c(S) \cdot \bar{y}(S).$$

- The probability that an element  $x \in X$  is covered satisfies

$$\mathbf{P}\left[x \in \bigcup_{S \in \mathcal{C}} S\right] \geq 1 - \frac{1}{e}.$$

## Proof of Lemma

Lemma

Let  $\mathcal{C} \subseteq \mathcal{F}$  be a random subset with each set  $S$  being included independently with probability  $\bar{y}(S)$ .

- The expected cost satisfies  $\mathbf{E}[c(\mathcal{C})] = \sum_{S \in \mathcal{F}} c(S) \cdot \bar{y}(S)$ .
- The probability that  $x$  is covered satisfies  $\mathbf{P}[x \in \cup_{S \in \mathcal{C}} S] \geq 1 - \frac{1}{e}$ .

Proof:

- Step 1:** The expected cost of the random set  $\mathcal{C}$

$$\begin{aligned} \mathbf{E}[c(\mathcal{C})] &= \mathbf{E}\left[\sum_{S \in \mathcal{C}} c(S)\right] = \mathbf{E}\left[\sum_{S \in \mathcal{F}} \mathbf{1}_{S \in \mathcal{C}} \cdot c(S)\right] \\ &= \sum_{S \in \mathcal{F}} \mathbf{P}[S \in \mathcal{C}] \cdot c(S) = \sum_{S \in \mathcal{F}} \bar{y}(S) \cdot c(S). \end{aligned}$$

- Step 2:** The probability for an element to be (not) covered

$$\begin{aligned} \mathbf{P}[x \notin \cup_{S \in \mathcal{C}} S] &= \prod_{S \in \mathcal{F}: x \in S} \mathbf{P}[S \notin \mathcal{C}] = \prod_{S \in \mathcal{F}: x \in S} (1 - \bar{y}(S)) \\ &\leq \prod_{S \in \mathcal{F}: x \in S} e^{-\bar{y}(S)} \quad \text{[}\bar{y} \text{ solves the LP!]} \\ &= e^{-\sum_{S \in \mathcal{F}: x \in S} \bar{y}(S)} \leq e^{-1} \quad \square \end{aligned}$$

$1 + x \leq e^x$  for any  $x \in \mathbb{R}$

## The Final Step

Lemma

Let  $\mathcal{C} \subseteq \mathcal{F}$  be a random subset with each set  $S$  being included independently with probability  $y(S)$ .

- The expected cost satisfies  $\mathbf{E}[c(\mathcal{C})] = \sum_{S \in \mathcal{F}} c(S) \cdot y(S)$ .
- The probability that  $x$  is covered satisfies  $\mathbf{P}[x \in \cup_{S \in \mathcal{C}} S] \geq 1 - \frac{1}{e}$ .

**Problem:** Need to make sure that every element is covered!

**Idea:** Amplify this probability by taking the union of  $\Omega(\log n)$  random sets  $\mathcal{C}$ .

WEIGHTED SET COVER-LP( $X, \mathcal{F}, c$ )

- compute  $\bar{y}$ , an optimal solution to the linear program
- $\mathcal{C} = \emptyset$
- repeat  $2 \ln n$  times
- for each  $S \in \mathcal{F}$
- let  $\mathcal{C} = \mathcal{C} \cup \{S\}$  with probability  $\bar{y}(S)$
- return  $\mathcal{C}$

clearly runs in polynomial-time!

## Analysis of WEIGHTED SET COVER-LP

Theorem

- With probability at least  $1 - \frac{1}{n}$ , the returned set  $\mathcal{C}$  is a valid cover of  $X$ .
- The expected approximation ratio is  $2 \ln(n)$ .

Proof:

- Step 1:** The probability that  $\mathcal{C}$  is a cover

- By previous Lemma, an element  $x \in X$  is covered in one of the  $2 \ln n$  iterations with probability at least  $1 - \frac{1}{e}$ , so that

$$\mathbf{P}[x \notin \cup_{S \in \mathcal{C}} S] \leq \left(\frac{1}{e}\right)^{2 \ln n} = \frac{1}{n^2}.$$

- This implies for the event that all elements are covered:

$$\mathbf{P}[X = \cup_{S \in \mathcal{C}} S] = 1 - \mathbf{P}\left[\bigcup_{x \in X} \{x \notin \cup_{S \in \mathcal{C}} S\}\right]$$

$$\mathbf{P}[A \cup B] \leq \mathbf{P}[A] + \mathbf{P}[B] \quad \geq 1 - \sum_{x \in X} \mathbf{P}[x \notin \cup_{S \in \mathcal{C}} S] \geq 1 - n \cdot \frac{1}{n^2} = 1 - \frac{1}{n}.$$

- Step 2:** The expected approximation ratio

- By previous lemma, the expected cost of one iteration is  $\sum_{S \in \mathcal{F}} c(S) \cdot \bar{y}(S)$ .
- Linearity  $\Rightarrow \mathbf{E}[c(\mathcal{C})] \leq 2 \ln(n) \cdot \sum_{S \in \mathcal{F}} c(S) \cdot \bar{y}(S) \leq 2 \ln(n) \cdot c(\mathcal{C}^*) \quad \square$

## Analysis of WEIGHTED SET COVER-LP

Theorem

- With probability at least  $1 - \frac{1}{n}$ , the returned set  $\mathcal{C}$  is a valid cover of  $X$ .
- The expected approximation ratio is  $2 \ln(n)$ .

By Markov's inequality,  $\mathbf{P}[c(\mathcal{C}) \leq 4 \ln(n) \cdot c(\mathcal{C}^*)] \geq 1/2$ .

Hence with probability at least  $1 - \frac{1}{n} - \frac{1}{2} > \frac{1}{3}$ , solution is valid and within a factor of  $4 \ln(n)$  of the optimum. probability could be further increased by repeating

Typical Approach for Designing Approximation Algorithms based on LPs

[Exercise Question (9/10).10] gives a different perspective on the amplification procedure through non-linear randomised rounding.

## Outline

Weighted Set Cover

MAX-CNF

## MAX-CNF

Recall:

MAX-3-CNF Satisfiability

- Given: 3-CNF formula, e.g.:  $(x_1 \vee x_3 \vee \bar{x}_4) \wedge (x_2 \vee \bar{x}_3 \vee \bar{x}_5) \wedge \dots$
- Goal: Find an assignment of the variables that satisfies as many clauses as possible.

MAX-CNF Satisfiability (MAX-SAT)

- Given: CNF formula, e.g.:  $(x_1 \vee \bar{x}_4) \wedge (x_2 \vee \bar{x}_3 \vee x_4 \vee \bar{x}_5) \wedge \dots$
- Goal: Find an assignment of the variables that satisfies as many clauses as possible.

Why study this generalised problem?

- Allowing arbitrary clause lengths makes the problem more interesting (we will see that simply guessing is not the best!)
- a nice concluding example where we can practice previously learned approaches

## Approach 1: Guessing the Assignment

Assign each variable true or false uniformly and independently at random.

Recall: This was the successful approach to solve MAX-3-CNF!

Analysis

For any clause  $i$  which has length  $\ell$ ,

$$\mathbf{P}[\text{clause } i \text{ is satisfied}] = 1 - 2^{-\ell} := \alpha_\ell.$$

In particular, the guessing algorithm is a **randomised 2-approximation**.

Proof:

- First statement as in the proof of Theorem 35.6. For clause  $i$  not to be satisfied, all  $\ell$  occurring variables must be set to a specific value.
- As before, let  $Y := \sum_{i=1}^m Y_i$  be the number of satisfied clauses. Then,

$$\mathbf{E}[Y] = \mathbf{E}\left[\sum_{i=1}^m Y_i\right] = \sum_{i=1}^m \mathbf{E}[Y_i] \geq \sum_{i=1}^m \frac{1}{2} = \frac{1}{2} \cdot m. \quad \square$$

## Approach 2: Guessing with a “Hunch” (Randomised Rounding)

First solve a linear program and use fractional values for a **biased** coin flip.

The same as **randomised rounding**!

0-1 Integer Program

$$\text{maximize } \sum_{i=1}^m z_i$$

$$\text{subject to } \sum_{j \in C_i^+} y_j + \sum_{j \in C_i^-} (1 - y_j) \geq z_i \quad \text{for each } i = 1, 2, \dots, m$$

These **auxiliary** variables are used to reflect whether a clause is satisfied or not

$C_i^+$  is the index set of the un-negated variables of clause  $i$ .

$$z_i \in \{0, 1\} \quad \text{for each } i = 1, 2, \dots, m$$

$$y_j \in \{0, 1\} \quad \text{for each } j = 1, 2, \dots, n$$

- In the **corresponding LP** each  $\in \{0, 1\}$  is replaced by  $\in [0, 1]$
- Let  $(\bar{y}, \bar{z})$  be the optimal solution of the LP
- Obtain an integer solution  $y$  through **randomised rounding** of  $\bar{y}$

## Analysis of Randomised Rounding

Lemma

For any clause  $i$  of length  $\ell$ ,

$$\mathbf{P}[\text{clause } i \text{ is satisfied}] \geq \left(1 - \left(1 - \frac{1}{\ell}\right)^\ell\right) \cdot \bar{z}_i.$$

Proof of Lemma (1/2):

- Assume w.l.o.g. all literals in clause  $i$  appear non-negated (otherwise replace every occurrence of  $x_j$  by  $\bar{x}_j$  in the whole formula)
- Further, by relabelling assume  $C_i = (x_1 \vee \dots \vee x_\ell)$

$$\Rightarrow \mathbf{P}[\text{clause } i \text{ is satisfied}] = 1 - \prod_{j=1}^{\ell} \mathbf{P}[x_j \text{ is false}] = 1 - \prod_{j=1}^{\ell} (1 - \bar{y}_j)$$

Arithmetic vs. geometric mean:

$$\frac{a_1 + \dots + a_k}{k} \geq \sqrt[k]{a_1 \times \dots \times a_k}$$

$$\geq 1 - \left(\frac{\sum_{j=1}^{\ell} (1 - \bar{y}_j)}{\ell}\right)^\ell$$

$$= 1 - \left(1 - \frac{\sum_{j=1}^{\ell} \bar{y}_j}{\ell}\right)^\ell \geq 1 - \left(1 - \frac{\bar{z}_i}{\ell}\right)^\ell.$$

## Analysis of Randomised Rounding

Lemma

For any clause  $i$  of length  $\ell$ ,

$$\mathbf{P}[\text{clause } i \text{ is satisfied}] \geq \left(1 - \left(1 - \frac{1}{\ell}\right)^\ell\right) \cdot \bar{z}_i.$$

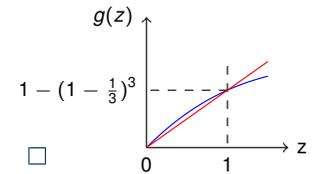

Proof of Lemma (2/2):

- So far we have shown:

$$\mathbf{P}[\text{clause } i \text{ is satisfied}] \geq 1 - \left(1 - \frac{\bar{z}_i}{\ell}\right)^\ell$$

- For any  $\ell \geq 1$ , define  $g(z) := 1 - \left(1 - \frac{z}{\ell}\right)^\ell$ . This is a **concave** function with  $g(0) = 0$  and  $g(1) = 1 - \left(1 - \frac{1}{\ell}\right)^\ell =: \beta_\ell$ .

$$\Rightarrow g(z) \geq \beta_\ell \cdot z \quad \text{for any } z \in [0, 1]$$

- Therefore,  $\mathbf{P}[\text{clause } i \text{ is satisfied}] \geq \beta_\ell \cdot \bar{z}_i$ .  $\square$

## Analysis of Randomised Rounding

Lemma

For any clause  $i$  of length  $\ell$ ,

$$\mathbf{P}[\text{clause } i \text{ is satisfied}] \geq \left(1 - \left(1 - \frac{1}{\ell}\right)^\ell\right) \cdot \bar{z}_i.$$

Theorem

Randomised Rounding yields a  $1/(1 - 1/e) \approx 1.5820$  randomised approximation algorithm for MAX-CNF.

Proof of Theorem:

- For any clause  $i = 1, 2, \dots, m$ , let  $\ell_i$  be the corresponding length.
- Then the **expected number** of satisfied clauses is:

$$\mathbf{E}[Y] = \sum_{i=1}^m \mathbf{E}[Y_i] \geq \sum_{i=1}^m \left(1 - \left(1 - \frac{1}{\ell_i}\right)^{\ell_i}\right) \cdot \bar{z}_i \geq \sum_{i=1}^m \left(1 - \frac{1}{e}\right) \cdot \bar{z}_i \geq \left(1 - \frac{1}{e}\right) \cdot \text{OPT}$$

By Lemma

Since  $(1 - 1/x)^x \leq 1/e$

LP solution at least as good as optimum

## Approach 3: Hybrid Algorithm

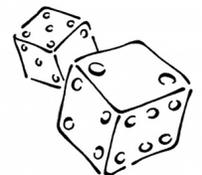

### Summary

- Approach 1** (Guessing) achieves better guarantee on **longer clauses**
- Approach 2** (Rounding) achieves better guarantee on **shorter clauses**

**Idea:** Consider a **hybrid algorithm** which interpolates between the two approaches

HYBRID-MAX-CNF( $\varphi, n, m$ )

- Let  $b \in \{0, 1\}$  be the flip of a fair coin
- If**  $b = 0$  **then** perform random guessing
- If**  $b = 1$  **then** perform randomised rounding
- return** the computed solution

Algorithm sets each variable  $x_i$  to TRUE with prob.  $\frac{1}{2} \cdot \frac{1}{2} + \frac{1}{2} \cdot \bar{y}_i$ .  
Note, however, that variables are **not** independently assigned!

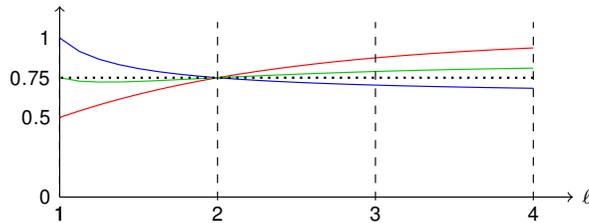

## Analysis of Hybrid Algorithm

Theorem

HYBRID-MAX-CNF( $\varphi, n, m$ ) is a randomised 4/3-approx. algorithm.

Proof:

- It suffices to prove that clause  $i$  is satisfied with probability at least  $3/4 \cdot \bar{z}_i$
- For any clause  $i$  of length  $\ell$ :
  - Algorithm 1 satisfies it with probability  $1 - 2^{-\ell} = \alpha_\ell \geq \alpha_\ell \cdot \bar{z}_i$ .
  - Algorithm 2 satisfies it with probability  $\beta_\ell \cdot \bar{z}_i$ .
  - HYBRID-MAX-CNF( $\varphi, n, m$ ) satisfies it with probability  $\frac{1}{2} \cdot \alpha_\ell \cdot \bar{z}_i + \frac{1}{2} \cdot \beta_\ell \cdot \bar{z}_i$ .
- Note  $\frac{\alpha_\ell + \beta_\ell}{2} = 3/4$  for  $\ell \in \{1, 2\}$ , and for  $\ell \geq 3$ ,  $\frac{\alpha_\ell + \beta_\ell}{2} \geq 3/4$  (see figure)
- $\Rightarrow$  HYBRID-MAX-CNF( $\varphi, n, m$ ) satisfies it with prob. at least  $3/4 \cdot \bar{z}_i$   $\square$

## MAX-CNF Conclusion

Summary

- Since  $\alpha_2 = \beta_2 = 3/4$ , we cannot achieve a better approximation ratio than 4/3 by combining Algorithm 1 & 2 in a different way
- The 4/3-approximation algorithm can be easily derandomised
  - Idea: use the conditional expectation trick for both Algorithm 1 & 2 and output the better solution
- The 4/3-approximation algorithm applies unchanged to a weighted version of MAX-CNF, where each clause has a non-negative weight
- Even MAX-2-CNF (every clause has length 2) is NP-hard!
